Cataloguing data

This publication (and any material sourced from it) should be attributed as: SFA, SFA/FSR/13, Fisheries Statistical Report, Year 2024, Seychelles Fisheries Authority, Victoria, Seychelles.

This publication is available at: https://sfa.sc/sfa-publications-and-other-fisheries-reports

Seychelles Fisheries Authority (SFA) is the leading agency responsible for the management, development, and sustainable exploitation of Seychelles' rich marine resources. Established in 1984, the SFA is dedicated to ensuring that the fisheries sector continues to thrive while preserving the delicate balance of the marine ecosystem. It is a parastatal organization with autonomous legal and financial status, supervised by a board of directors appointed by the President.

The functions of SFA as per Section 4 of the Seychelles Fisheries Authority Act, 2024 are:

- *promote, develop and regulate fisheries;*
- *advise the government on all matters related to fisheries; assist in the formulation of national policies with respect to*
- *fisheries and lead the implementation of these policies;*
- *assist in negotiations and represent Seychelles on matters related to fisheries;*
- *promote and conduct scientific and development research related to fisheries;*
- *enter into agreements in consultation with the authority responsible for ports, for the management or joint management of ports, harbours and related facilities;*
- *administer the laws relating to fisheries and aquaculture and regulations made thereunder and other written laws relating to fisheries; and*
- *advise the government on the manpower training requirements of Seychelles with regard to the fisheries sector.*

Executive Summary

Executive Summary

This report provides annual updates on fisheries statistics for industrial, semi-industrial, artisanal, sea cucumber, and lobster fisheries in Seychelles for the year 2025, including vessel activity, species composition, and geographical distribution. It also outlines data collection and processing procedures.

*In 2025, 49 licensed **purse seiners** operating in the WIO reported a total catch of 447,804 MT, up 20% from 2024 and the highest catch recorded in the past two decades. Despite a 5% reduction in fishing effort (11,423 fishing days), the mean catch rate increased from 31.25 to 39.20 MT/fishing day. The Spanish fleet accounted for 33% of total catches, followed by the Seychelles fleet (30%), vessels under private agreements (22%), and the French fleet (15%).*

The Seychelles-flagged fleet landed 134,240 MT in the WIO, a 16% increase over 2024, despite a reduction fishing effort resulting in a mean catch rate improved from 31.82 to 38.80 MT/fishing day.

Within the Seychelles EEZ, total purse seine catches declined by 14% to 79,798 MT, reflecting a 34% reduction in fishing effort. However, the mean catch rate increased from 23.57 to 30.66 MT/fishing day.

Species composition remained stable, with skipjack tuna (62%) dominating catches, followed by yellowfin (29%) and bigeye tuna (7%). Catches of all three major target species increased, with skipjack catches increasing by 21%, yellowfin by 10%, and bigeye by 34%.

Port Victoria remained the main tuna landing and transhipment hub in the WIO, handling 412,076 MT in 2025, a 24% increase from 2024 and representing 94% of all tuna unloaded. Of this volume, 76% was transhipped for export and 24% was landed locally for processing, storage, or sale.

*In 2025, 100 licensed **industrial longliners** operating in the WIO reported an estimated catch of 21,695 MT from 44.4 million hooks, yielding a mean catch rate of 0.49 MT/1,000 hooks. This represents a 5% increase in catches and a 26% increase in fishing effort compared with 2024.*

Of the total catch, 12,650 MT (58%) was taken inside the Seychelles EEZ, representing a 16% decrease from 2024 despite a 14% increase in fishing effort, resulting in a lower catch rate of 0.48 MT/1,000 hooks.

Bigeye tuna was the dominant species, accounting for 44% of total catches, followed by yellowfin tuna (30%), other species (14%), and swordfish (6%). Compared with 2024, catches of bigeye tuna, swordfish and other species increased, while yellowfin tuna catches declined.

The Seychelles-flagged fleet contributed 14,768 MT, a 27% increase over 2024. An estimated 29.0 million hooks were deployed, yielding a mean catch rate of 0.51 MT/1,000 hooks.

*The **semi-industrial fishery** recorded a total catch of 1,965 MT in 2025, a 6% decrease from 2024, corresponding to a 9% reduction in fishing effort to 6.2 million hooks. Despite lower catches, the mean catch rate increased slightly to 0.32 MT/1,000 hooks. Yellowfin tuna dominated catches (79%), followed by bigeye tuna (11%) and swordfish (4%).*

*The **artisanal fishery** landed 4,077 MT in 2025, a 12% decrease from 2024 despite relatively stable vessel activity. Schooners (40%) and outboard vessels (39%) remained the main contributors to total catches. Handlines remained the dominant gear, accounting for 73% of landings, followed by encircling gillnets (18%) and traps (8%). While handline and trap catches declined, gillnet catches increased by 29%.*

Key species landed were trevally (23%), jobfish (18%), Indian mackerel (13%), and emperor red snapper (11%). Trevally and jobfish catches declined, while Indian mackerel landings increased substantially.

*The 2025/2026 **sea cucumber** fishing season recorded a total landing of 183,899 pieces, compared to 181,588 pieces in the 2024/2025 season. Flower Teatfish constituted the largest proportion with 146,789 pieces in 2024/2025 and 151,399 pieces in 2025/2026. This was followed by Prickly Redfish at 27,231 pieces in 2024/2025 and 23,682 pieces for the 2025/2026 fishing season. For the 2024/2025, a total of 3,286 pieces of Golden Sandfish were landed and 6,888 pieces were landed for the 2025/2026 season. A total of 3,286 pieces of White Teatfish pieces were landed in 2025/2026 and 1,611 pieces in 2025/2026, while Black Teatfish accounted for only 657 pieces in 2024/2025 and 319 pieces in 2025/2026*

In the 2024/2025 season, 112 trips were completed, representing a decrease of 25 trips compared to the 2023/2024 season (137 trips), which was 10 trips more than the 2022/2023 season. In the 2025/2026 fishing season the number of trips were only 92 trips, which was a noticeable decline compared to previous years.

*In the 2023/2024 fishing season, total landing of the **lobster fishery** reached 3.32 MT, representing a 62% increase compared to 2021/2022 season (2.05 MT), but a 46% decrease from the peak of 6.14 MT recorded in 2020/2021. Historically, the lowest catch was 0.61 MT in 2013/2014 season.*

Species composition in 2023 was dominated by Panulirus penicillatus, contributing 2.21 MT (66.8%) of the total catch, followed by P. longipes at 1.0 MT (29.6%). P. versicolor and P.

ornatus were less abundant, accounting for 0.07 MT (2.2%) and 0.05 MT (1.4%), respectively.

Snorkelling remained the primary fishing method, responsible for 95% of the total catch.

*In 2025, Seychelles' **fisheries exports** expanded strongly, with export volume increasing by 76% to 110,695 MT and export earnings rising by 24% to SCR 5.4 billion. Growth was driven primarily by a 419% increase in fresh and frozen fish exports, while sea cucumber exports more than doubled in volume. In contrast, canned tuna exports declined by 6% in volume and 5% in value, although it remained the largest export product, accounting for 67% of total export earnings. Export markets also became more diversified, particularly for fresh and frozen fish and fish meal, while Europe remained the main destination for canned tuna and East Asia the principal market for sea cucumber.*

***Fish and fish product** imports fell by 28% to 50,158 MT in 2025, while import value increased by 10% to SCR 2.1 billion, reflecting higher import prices. Fresh and frozen fish remained the dominant import category, while crustacean and mollusc imports increased. Spain became the leading supplier of fresh and frozen fish, overtaking France, while India remained the main source of crustacean imports. Overall, higher import expenditure was driven by rising prices rather than increased import volumes.*

***Vessel expenditures** associated with the fisheries sector remained significant in 2025. **Bunkering sales** increased by 7% in volume to 199,720 MT but declined slightly in value to SCR 2.57 billion due to lower fuel prices. Excluding bunkering, vessel expenditures increased by 26% to SCR 397.8 million, driven largely by higher port dues following the implementation of revised harbour tariffs. Purse seiners continued to account for the largest share of port-related expenditures (87%), while reefer vessel expenditure increased substantially in response to greater reliance on reefer carriers for tuna exports.*

Introduction

The Seychelles Fisheries Statistical Report is a comprehensive source of information for the commercial fishing industry, fisheries managers, policymakers, and researchers. Since 2014 the report has presented annual updates of fisheries statistics. The report contains data on the fish production from Seychelles artisanal, semi-industrial, industrial longline and purse seine fishery by vessel type, species, and geographical locations. Profiles of each fishery, summary of data collection and processing procedures are also provided.

In this edition, information on the sea cucumber and lobster fisheries has been added as new Sections 5 and 6, respectively. In addition, fisheries economic statistics have been included, covering the export and import of fish and fish products in section 7 and 8, as well as vessel bunkering and port expenditures by fishing-related vessels in section 9. Information on the sport fishery will be incorporated progressively in future editions.

Readers should note that some figures presented in this bulletin may be different to those previously published because these figures may have been revised during thorough verifications carried out on the data following database upgrading, new data received that were previously missing, revised EEZ shape file used or data validation using VMS data. Also, some of the figures presented may be subject to revision (usually upwards) as more data become available.

Since space is a limiting factor, in some tables, flag country appearing in these tables is included based on their total catch. The remaining flags are classified under “OTHERS”. Flag countries with only one vessel are automatically placed under “OTHERS” to preserve the confidentiality of data pertaining to the vessel.

In addition to this report, fisheries statistics are also made available through the SFA Fisheries Information Management System (FIMS). FIMS is an interactive web-based platform developed to facilitate the sharing and dissemination of fisheries information to the general public. The platform provides users with access to statistical tables, summaries, charts, and other fisheries-related information in a user-friendly and dynamic format.

One of the key advantages of FIMS is that it provides access to more up-to-date information. While the annual report is published during the last quarter of the following year to allow for data verification and validation, FIMS is updated periodically as preliminary data become available for publication. This enables stakeholders to access the latest fisheries statistics and trends in a timely manner while awaiting the release of the final annual report.

The FIMS platform forms an important component of SFA's ongoing efforts to enhance transparency, improve access to fisheries information, and support evidence-based decision-making within the fisheries sector. The system can be accessed online at: https://sfa-fims.traseable.com/.

Purse Seine Fishery:

Tuna purse seiners started exploratory fishing operation in Seychelles EEZ since the early 1980s. Commercial purse seining activities in the Seychelles EEZ began in 1984 when French and Spanish fleets moved from the tropical Atlantic to the Western Indian Ocean. The main fishing nation involves in purse seining in the WIO were those operating under the European Economic Community Agreement (French and Spanish). Seychelles registered purse seiners started fishing in 1997 and are currently of Spanish ownership.

Traditionally, purse seiners fished over free-swimming schools until the 1990s where changes were introduced to the fishing strategy, with the extensive use of floating objects such as Fish Aggregating Devices (FADs). The composition of species and size resulting from this type of fishing varies considerably in comparison to traditional fishing over free schools, since skipjack is the main catch and there is a higher rate of smaller yellowfin and bigeye. The purse seine tuna fishery targets mostly surface swimming yellowfin and skipjack tuna.

In view of Port Victoria's strategic location in the middle of the tuna fishing grounds, Port Victoria remain the most important tuna transhipment port in the Indian Ocean. Over 90% of catches of purse seiners licensed to fish inside the Seychelles EEZ are transhipped and landed in Port Victoria every year.

Data Collection

Data sources for tuna purse seiners are logbooks, transhipment, well plans and biological sampling. Logbooks are completed by the captains and contains record of the vessel's daily activities submitted to SFA. The logbook must be completed by vessel's captain for each trip undertaken during the period the vessel is registered as a Seychelles Flagged vessels for Seychelles flagged vessels and for the period of license for foreign vessels. All details must be filled in for each activity undertaken daily. Activity includes fishing sets and activities on FAD's, and it must be completed before the boat docks at the end of each trip. When the vessels are not fishing, a blank logbook must be submitted to SFA for the non-fishing period stating reason for not fishing. It must be noted that the supply vessels, vessels assisting the purse seiners during their fishing trip, must also complete a similar logbook and submit to SFA.

Landing and transhipment information can be obtained from either the local representative (agent) of the vessel or the vessel owner. They provide details of unloaded catch for each vessel and each operation.

The well plans contain information on where the catches are stored on the vessel. This is important for the port sampling program.

The multi-species nature of tropical tuna surface fisheries (purse seine) gives rise to a series of difficulties at the time of estimating basic catch by species and catch by size statistics. Complications are mainly due on one hand to the unreliability of the weight and species

composition declared on the logbooks (eye estimate of skippers) and to the tendencies of classifying landings into commercial categories, solely according to the sizes of individual rather than according to both size and species. For example, fish < 5kg often contains small yellowfin and bigeye as well as skipjacks but are often declared as skipjack only. To improve the accuracy of statistics for sound stock assessment, it is essential to implement a tuna-sampling programme. Biological sampling is carried out to simultaneously estimate the species composition (by counting and identifying each species) and the length frequency distribution (by measuring the individuals) of the catch. Using the logbooks and well plans, the fisheries technician decides, depending on established protocol the wells that are suitable for sampling. The criteria are:

- types of association (free schools or FAD's associated schools)
- zone covered, (10 zones),
- season (according to the quarter of the year)
- weight class of individuals (< 5kg, 10 – 30 kg, >30kg etc.)

The wells to be sampled must contain fish that were; caught from the same type of association, same zone, and same season. Furthermore, priorities are set depending on zones and season previously covered. The final decision is then made on site, depending on which vessel or wells being unloaded at that time.

Data Processing

Data management for the purse seine fishery has evolved significantly over the past two decades through close collaboration with the Institut de Recherche pour le Développement (IRD) in France. A major milestone was achieved on 1st July 2024, when SFA successfully implemented the OBSERVE software across all industrial fisheries. This advanced system now manages data for both industrial and semi-industrial fisheries, integrating information from fishers' logbooks, well plans, port sampling, landings, transshipments, and scientific observer programs.

Originally introduced in 2013 to handle observer data for purse seiners, OBSERVE has been expanded to provide a unified platform for comprehensive data management. The software includes built-in error detection mechanisms at the data capture stage, significantly reducing data entry errors. Following initial capture, purse seine data undergo verification and validation using AKADO2, a specialized tool, upgraded in 2024 for compatibility with OBSERVE. AKADO2 also validate activity positions declared in logbooks against VMS (Vessel Monitoring System) data, ensuring spatial accuracy.

After validation, data are processed using custom R scripts to extrapolate logbook records to total landings and transshipments. A raising factor, calculated by dividing total landed/transhipped catches by logbook-declared catches per trip, is applied to logbook estimate total catches by geographical location. While this method adjusts for reporting discrepancies, it does not correct species composition, which remains based on logbook declarations.

- Readers should note that the t*otal <u>tuna transhipped</u> in Port Victoria refers to the total volume of fish transhipped from purse seiners to reefers or to containers, whereas "landings" are volume of fish landed in the port for further processing by*

local companies or for sale.

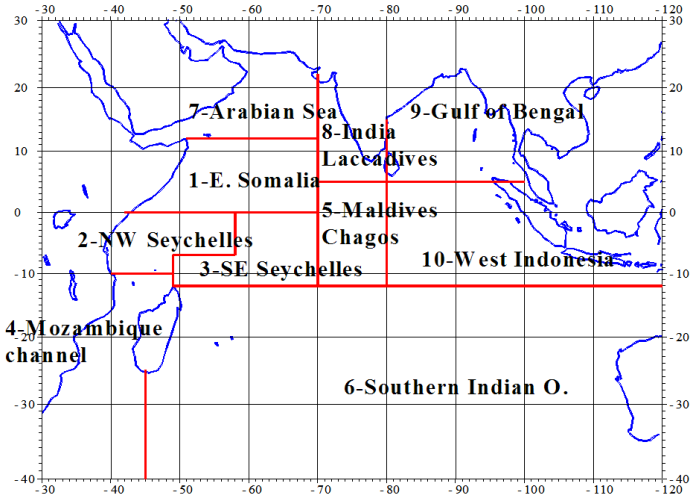

- *Vessels covered or active* refer to vessels for which a logbook has been received and processed.

- The total *number of vessels licensed and covered* may not correspond to the direct summing of number of vessels licensed or vessel covered by countries by month or by year. The reason for this is that a vessel may change licence from one country to another in the same month, hence counted under both countries for that month or year.

- Where a trip is spread over two different years, e.g., December 2023 - January 2024, the catch up to December 2023 will be attributed to the year 2023 and the catch made in January 2024 will be attributed to the year 2024. However, the transhipment/landing will be attributed to the year when that transhipment/ landing actually occurs. This explains the difference between the total catch for a given year and the total catch transhipped or landed in that same year.

- The figures presented in this report for landings and transshipments may differ slightly from previously published data. This is due to updates that include revised discards and bycatch data reported during unloading. However, the Seychelles Fisheries Authority (SFA) cannot publish discards and bycatch data disaggregated by species during unloading, nor discards recorded in logbooks, as this information is not yet consistently provided by all vessels. It is important to note that in previous years, some vessels reported both bycatch and discards under the category of "discards." Since 2022, most vessels have started reporting bycatch and discards separately. Therefore, figures for bycatch and discards are not directly comparable to those from previous years.

- Maps showing the Zones of Indian Ocean for Purse seine fishery

Industrial Longliners Fishery:

Industrial longline fisheries comprise of foreign longline vessels licensed to fish in Seychelles EEZ which started to be issued in the early 80' and Seychelles registered vessels (Taiwanese origin) started operating in 1999. Presently Taiwan Province of China and Seychelles registered fleet are the primary industrial longline fleets licensed to operate in the Seychelles Waters.

The longline gear used by the industrial longliners consists of three basic components: the mainline, the branch line, and the baited hook. All these parts are adaptable for targeting specific species through changes in materials, lengths, and deployment strategies. Using small buoys and float lines to suspend the gear below the surface results in a pelagic longline set that targets large pelagic fishes, such as bigeye (Thunnus obesus), yellowfin (Thunnus albacares), and albacore (Thunnus alalunga), broadbill swordfish (Xiphias gladius), and other billfishes.

Data Collection

The main data sources for the longline fishery are logbooks, landings and transhipment declarations and length frequency forms. Those vessels almost never call into port Victoria, and their data are submitted to SFA electronically. Logbooks are distributed by SFA to all longliners either licensed to fish in the Seychelles EEZ or registered in Seychelles. All longliners licensed to fish inside of the Seychelles Exclusive Economic zone is under obligation to submit a logbook to the Seychelles Fisheries Authority for the whole duration of their licensed period. The logbook details their daily catch and effort whilst inside of the Seychelles EEZ and state when they are outside the EEZ or in Port. Seychelles registered vessels are under obligation to submit a logbook detailing their daily activities, catch and effort wherever they operate throughout the validity of their registration period

In addition, a sampling protocol (self-reporting) with aim to collect information on the size distribution of the different species (tuna, billfish, and sharks) caught, to monitor the stock structure relative to time and strata, was set up by SFA in collaboration with Deep-Sea Fisheries of Taiwan in June 2007. The sampling is carried out on Seychelles Flagged vessel by crew members. They measure the first 30 fish per each set hauls and record on a sampling form which is submitted to SFA by email on a weekly basis.
The data recorded are Vessel details, Date, Position, and the measurement for the first 30 fish by species using a flexible measuring tape (FT). The measurement type varies by species as follows:

- For Tuna species : Upper-jaw fork length (FL) - Straight distance between the tip of the upper jaw and the fork of the tail
- For billfishes: Lower-jaw fork length (LJ) - Straight distance between the tip of the lower jaw and the fork of the tail
- For Sharks: total length (TL) -Straight distance between the anterior-most part of the fish and the end of the caudal fin rays when compressed dorso-ventrally

Data Processing

Effective 1st July 2024, all industrial longline fishery data were integrated into the OBSERVE data management system, similar to the purse seine fishery. OBSERVE now manages comprehensive datasets, including fishers' logbooks, onboard sampling, landings, and transshipment records for purse seine, industrial longline and semi-industrial longline fisheries. To streamline data transfer, SFA has also developed a web based platform , LTO, software during the year 2025 to automatically import logbook records submitted in Excel format into OBSERVE for the Seychelles-flagged industrial longliners to Observe.

Following data capture, a series of rigorous verification steps are applied using custom R scripts developed specifically for industrial longline data. These scripts identify and exclude potential data entry errors. Furthermore, the geographical positions of fishing activities reported by skippers are validated against VMS data. This cross-check ensures accuracy and helps detect falsified or erroneous logbook entries.

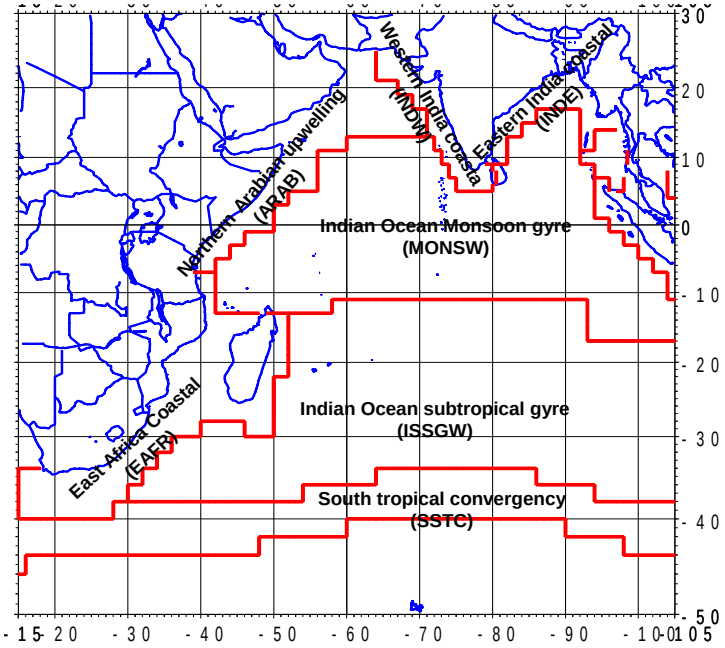

Once validated, data are processed using advanced R scripts (developed in 2024–2025) to estimate final catches for the fishery. Logbook-reported weights typically reflect processed fish (e.g., headed and gutted or gilled). To standardize reporting, whole fish weights are estimated using conversion factors established by the Indian Ocean Tuna Commission (IOTC).

- For industrial longliners, each month covered in a logbook is considered as one logbook.

- Readers should be aware that the longliners statistics represent only a small sample of longliners activity in the WIO because:

    - Not all longliners in the WIO have a license to fish in the Seychelles EEZ and therefore are under no obligation to report to SFA.
    - Some Distant Water Fishing Nations (DWFN) provide SFA with log sheets covering their activity in the entire Indian Ocean while others confine their report to the Seychelles EEZ only.

- Maps showing the Zones of Indian Ocean for Longline fishery.

Longhurst areas

Semi Industrial Longline Fisheries

The semi-industrial sector comprises of the monofilament longline fishery operating around the Mahe plateaux which started in 1995. On average these vessels remain at sea for a period of 10 days, preserving their catches on ice. This fishery has been developed with the objective of relieving pressure from demersal resources by targeting pelagic fish in deep waters outside the continental plateaux.

The semi-industrial longline gear is used to target large pelagic fishes, such as broadbill swordfish (*Xiphias gladius*), bigeye (*Thunnus obesus*) and yellowfin tuna (*Thunnus albacares*). For trips targeting swordfish and tuna, bycatch (species not targeted but captured) of billfishes (*istiophorid*) such as marlins and sailfish and other species are also caught.

Data Collection

The semi-industrial longline fishery is monitored through a logbook system. Logbooks are distributed by SFA to all skippers of semi-industrial longliners and are collected by fisheries statistical technicians upon the arrivals of the vessel from its fishing trip. The logbook provides most of the fishing trip general information, and the day-by-day catch and effort information. Landing forms from fish processors and fish mongers are also collected for the trips and is used in data processing to obtain the actual catches of the fishery.
In addition, a sampling protocol with aim to collect information on the size distribution of the different species (tuna, billfish, and sharks) caught, to monitor the stock structure relative to time and strata, was set up by SFA since the beginning of the fishery. The sampling is carried out during landing by SFA sampling team where the fish are measured using a calliper (CA).
The measurement type varies by species as follows:

- For Tuna species : Upper-jaw fork length (FL) - Straight distance between the tip of the upper jaw and the fork of the tail
- For billfishes:
  - Pectoral anal length (PAL) - Straight distance between the anterior insertion of the pectoral fin and the posterior rim of the anal fin
  - Lower-jaw fork length (LJ) - Straight distance between the tip of the lower jaw and the fork of the tail
- For Sharks: total length (TL) -Straight distance between the anterior-most part of the fish and the end of the caudal fin rays when compressed dorso-ventrally

Data Processing

Effective 1st July 2024, all semi-industrial longline fishery data were integrated into the OBSERVE data management system, similar to the industrial longline fishery. OBSERVE now manages comprehensive datasets, including fishers' logbooks, port sampling data, and

landing records for the semi-industrial fishery, providing a centralized platform for improved data accuracy and accessibility.

Following data capture, rigorous verification steps are applied using custom R scripts developed specifically for semi-industrial longline data. These scripts identify and eliminate potential data entry errors. Additionally, the geographical positions of fishing activities reported by skippers are validated against VMS (Vessel Monitoring System) data. This cross-check ensures spatial accuracy and helps detect falsified or erroneous logbook entries.

Once validated, data are processed using advanced R scripts (developed in 2024–2025) to estimate final catches for the fishery. Logbook-reported weights typically reflect processed fish (e.g., headed and gutted or gilled). To standardize reporting, whole fish weights are estimated using conversion factors established and approved by the IOTC.

Finally, estimated catches reported in logbooks are raised to total landed catches using a calculated raising factor, providing the final estimated catch for the fishery.

Artisanal Fishery:

In 2024, the Seychelles Fisheries Authority (SFA) upgraded its data processing system for the artisanal fishery. As a result, SFA is currently reprocessing historical artisanal fishery data to produce more refined and disaggregated statistics. This reprocessing is a time-consuming task and will be carried out in phases. Consequently, this report includes only the data for the years 2018 to 2024 that have been processed using the new system. Readers should be aware that the estimates presented in this report may differ from previously published figures.

The artisanal fishery of the Seychelles is characterized by a wide variety of boats using different gears and catching various species within the Seychelles EEZ. The principal gears used by whalers and schooners are handlines, while the small boats use a multitude of gear combinations, including handlines, traps, encircling gill nets, beach seines and harpoons.

Small boats usually operate within 10 nm of the granitic islands, the ‘inshore’ area, and often in waters adjacent to the vessel mooring and landing sites used. Schooners and whalers target offshore banks and the outer islands, with catches often landed in Port Victoria, Providence Port, or the larger landing sites. Depending on the season and species targeted, whalers may also operate inshore and within or close to the strata where they are based.

All the artisanal fishing vessels target demersal resources such as Lutjanids (snappers), serranids (groupers), lethrinids (capitaines), Scombridae (notably the Indian mackerel), Siganidae (rabbitfish), Lethrinidae (emperors), Sphyraenidae (barracuda)and carangidaes (carangues). The catches supply the local market demand including hotels and restaurants, and some species such as groupers and snappers are exported.

It is to be noted that there are no discards in the artisanal fishery as the fish that are not sold are used as bait or are kept for own consumption by the fishers.

Data Collection

The artisanal fisheries are monitored through a Catch Assessment Survey (CAS) stratified by geographical area, vessel type, and gear type. This system is supplemented by data collected from fishmongers and companies involved in the processing and export of catches from the artisanal fishery. In addition, certain licensed fisheries, such as the spanner crab and dropline fisheries, are monitored through a logbook system, whereby vessel captains record fishing activities during each trip and submit completed logbooks upon their return. Readers should note that the statistics currently do not include catches from the sport and recreational fisheries.

The primary objective of the CAS is to collect boat activities, catch, effort, and species composition data to enable timely monitoring and assessment of status and trends in the major artisanal fisheries. The main inner granitic islands of Mahé, Praslin and La Digue, where more than 99% of the population resides, are covered by the surveys. Area stratification is the same for all boat types, whereby the three main islands are further divided into seven strata in relation to the location of landing sites, as follows:

- Mahé (4 strata).
    - MNW – Mahé northwest from Baie Ternay to Glacis;
    - MNE – Mahé northeast from La Retraite to Petit Paris;
    - ME – Mahé east from Cascade to Anse Forban;
    - MW – Mahé west from Takamaka to Port Glaud;
- Praslin/La Digue (3 strata);
    - PNE – Praslin northeast from Anse Boudin to Consolation;
    - PNW – Praslin northwest from Anse Takamaka to Anse Lazio,
    - LD – La Digue Island.

Nested within these strata are a total of 39 landing sites. Landing sites are divided into primary and secondary levels depending on the number of boats and catch landed at the site. A wide variety of species are monitored by the CAS and are collected disaggregated by species.

The Enumerators at designated landing sites collect data on:

- Weekly vessel activities: Information of all vessel's activities based on the site are collected through observations at the landing sites and interviews with Fishers present. The vessel activities are collected by vessel registration number, their activity, gear type and targeted species.

- Trip and Effort Details: Trip and effort information are collected through interviews of the fishers and includes trip dates and time, fishing effort, gear type and number and geographical information.

- Catch sampling data: Catch data are collected by random sampling whereby boat landing their catches at the time the enumerators are present at site. The catch from each boat selected is weighed and recorded by species. If the catch is landed in packets, a maximum of 5 packets per vessel must be weighed for each species-group and the total number of packets must be recorded. In the case of packets with mixed species, the total weight of the packet is recorded, and the enumerators estimate the proportion of each species in the packet. Where catches are landed as single fish, as many fish as possible must be weighed and recorded for each species-group, and the total number of fish is recorded by species. Samples must always be taken in a random manner. For any boat sampled, the enumerator must be present at the landing site so that the totality of the catch for the boat is estimate.

- Economic data: Data on expenses for the trip are collected through interviews with the fishers and sales data are collected at the landing sites or from fishmongers and fish processors.

- Biological data: Length frequency data collected by enumerators are for tuna and tuna-like species only for IOTC reporting obligations. Biological data for other species are collected by SFA research department.

Enumerators work six days a week and receive overtime pay or are scheduled for one day off during the week and on Sunday. Each week, they monitor a total of 39 sites, which include 12 primary and 27 secondary sites. While each enumerator covers one primary site per day, a single enumerator may cover two secondary sites in a day.

Data Processing

Since 2017, the Seychelles Fishing Authority (SFA) has enhanced its data collection system for the artisanal fishery. The Enumerators now use the advanced “Système d’Information Halieutiques” (SIH), developed in collaboration with IFREMER, France, to collect and capture various types of data in a disaggregated format. This upgrade has significantly improved the accuracy and detail of the data collected.

In 2022, the SIH was further upgraded to a web-based version and expanded to include data management for other coastal fisheries, notably sea cucumber and lobster fisheries. The web-based SIH enables enumerators to capture data at landing sites using tablets, allowing the SFA to access the data in real-time. The collected data are stored in the Allegro database, where the latter is verified and validated prior to estimating the total catch for the artisanal fishery. In 2025, SIH was further enhanced to incorporate data capture from logbook systems for emerging fisheries, particularly spanner crab, dropline and octopus fisheries.

In 2024, the SFA also upgraded its data processing system to improve estimates of total catch and effort for the artisanal fishery. The revised system includes additional validation procedures and the integration of VMS data to account for fishing trips missed during landing site observations.

The data processing steps involve reconstructing the monthly activity calendar for each vessel using information recorded by technicians on-site and VMS data. Fishing effort and catches are estimated through data extrapolation. Sample catch and effort data are extrapolated to the total reconstructed fishing trips to estimate total catches, effort, and species composition for the artisanal fishery by vessel type, landing site, gear type, and month.

- As a result, SFA is currently reprocessing historical artisanal fishery data to produce more refined and disaggregated statistics. This reprocessing is a time-consuming task and will be conducted in phases. Consequently, this report includes only the data for the years 2018 to 2024 that have been processed using the new system. Readers should be aware that the estimates presented in this report may hence differ from previously published figures.

- This phased approach ensures that the data is meticulously reviewed and updated, providing more accurate and detailed insights into the artisanal fishery.

Sea Cucumber Fishery

Sea cucumber harvesting in Seychelles dates to the early 1800s, but the fisheries remained small scale until the late 1990s, when a rapid increase in catch was observed. The increase in demand and price for "beche-de-mer" (dried body wall) led to an evolution in the fishery from the collector type, where fishers collected on foot in shallow areas, to the use of scuba gears as they moved to deeper areas. The higher value species are White teatfish (*Holothuria fuscogilva*), Black teatfish (*Holothuria nobilis*) and Flower teatfish (*Holothuria*. spp. (type "Pentard"). Prior to 1999, the fishery was open to all with no management restrictions in place. Declines in catch raised concerns about potential overexploitation of the resources, prompting the establishment of management measures to regulate the fishery. Regulations have been changed and improved over the last 20 years based on both fisheries dependent and independent stock assessments.

The current management regulations for the fishery include:

- A limit of 25 non-transferable fishing licenses and 3 processing licenses
- 8-9 months open fishing season.
- Restrictions to only 3 species allowed to be exploited – For the 2023/2024 and 2024/2025 fishing season the species were Flower teatfish, Pricky redfish (*Thelenota ananas*) and Golden sandfish (*Holothuria lessoni*).
- A Total Allowable Catch (TAC)
    - The quota in the Authorised Zones for the 2023/2024 and 2024/2025 fishing seasons were 240,475 pieces of Flower teatfish, 45,000 pieces of Prickly

redfish and 100,000 pieces of Golden Sandfish. The Authorised Zones consist of the Seychelles Bank, Platte Island, Coetivy Island and the Amirantes Bank

- In 2023/2024 and 2024/2025 fishing seasons an additional quota was allocated in zones outside of the Authorised Zones with prior written approval. The quota consists of 2500 pieces of Flower Teatfish, 1200 pieces of Prickly Redfish, 4000 pieces of Golden sandfish per licensee. Additionally, a quota of 1750 pieces were allocated for White Teatfish and 250 pieces for Black Teatfish

Licensed vessels are required according to their license conditions to adhere to these regulations and to provide catch and effort data to the SFA. Catches are sold to licensed processors where the sea cucumbers are prepared for exportation. Majority of the processed sea cucumber is sold to foreign markets.

Data Collection

Catch and effort data is collected through paper logbooks that are distributed to skippers during the vessel departure inspection at the beginning of a fishing trip and collected during the landing inspection at the end of the fishing trip. Training is given in how to fill the logbooks at the opening of each fishing season and whenever there are changes in skippers. Scuba diving is the only fishing method currently being used to collect sea cucumbers. Following a dive, the logbook needs to be filled out with the following information,

- Diving date
- Fishing site either using GPS position or the fishing grid provided by SFA.
- Start and end diving time.
- Number of divers
- Depths
- Dive time for each diver
- Catch in numbers of individual species.

Landings catch data is also collected during routine inspection conducted by MCS officers whenever a vessel is offloading. The data includes catch in numbers and in weight by species.

Data Processing

Data collected from paper logbooks are captured in the SIH-OBSDEB database by the Fisheries Research Department. Following data capture, the data is verified to ensure that any data entry errors are corrected. Landings data is recorded in an excel spreadsheet. All catch data presented in this report is based on landings data.

Data presented in this report will be for both the 2023/2024 and 2024/2025 fishing seasons.

Lobster Fishery

The Seychelles artisanal spiny lobster fishery targets shallow water lobster stocks around the main granitic islands. Locally, there are four species being exploited, notably, Pronghorn spiny lobster (*Panulirus penicillatus*), Long-legged spiny lobster (*Panulirus longipes*), Painted spiny lobster (*Panulirus versicolor*), and Ornate spiny lobster (*Panulirus ornatus*).

Data Collection

During the lobster fishing season data are collected from fishermen operating on Mahé, Praslin and La Digue through two main sources:

a) **Fisher Catch and Effort log (FCEL)**: Each licensed fishermen is given a logbook to record information on their fishing activities. Information collected included information on catch, effort, and fishing location.
b) **Sampled Catch and Effort log (SCEL)**: SFA research technicians sampled the landed catch directly whenever possible. Information on the species caught, weight and carapace length measures are collected. Interviews are also conducted to determine total effort and fishing location.

The lobster fishery operates on a seasonal and licensed basis; typically, the open season usually lasts for 3 months (December to March), however, the season length can vary depending on the state of the fishery. The 2021/2022 fishing season opened for a period of 4 months from the 21st of December 2020 to the 20th April 2021(inclusive of a 1-month extension). A total of 16 licenses were on offer, among which 13 were on Mahe, 2 for Praslin and 1 for La Digue. Since 2011 a compliance bond of SCR5000 was introduced to ensure that licence holders comply to the license conditions such as the submission of all their logbooks at the end of the fishing season.

Fishing activity is carried out from dusk around 6pm to dawn 5am, by 2 to 4 fisherman using outboard engine vessel (often Mini Mahé). The permitted method of fishing in this fishery includes snorkelling, scuba dive and bamboo traps.

Data Processing

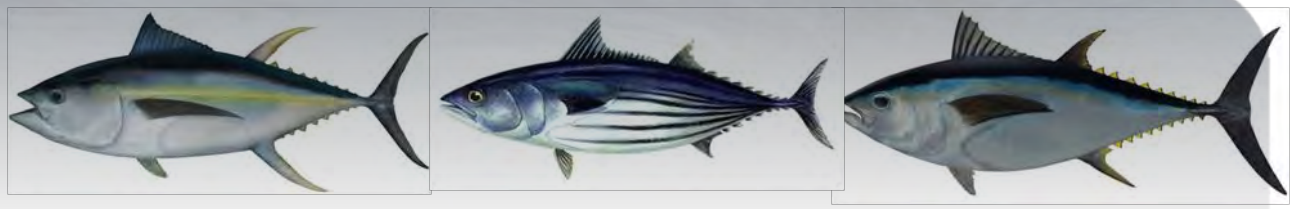

The collected data is captured in an access database and following capture the data is verified to correct any data entry errors. The information collected from the FCEL and the SCEL were crosschecked to determine the number of lobsters not sampled for each fishing trip. The average weight for each species was derived from the total weight and total number of lobsters (per species) recorded from the SCEL. The weight of lobsters not sampled for each fishing trip was estimated by raising the average weight of each species to the total number of that species caught. The total catch of lobsters was derived from the sum of weights of lobsters from the SCEL and the total sum of the raised weight of lobsters not sampled. The total effort was based on the total number of fishing trips undertaken. The catch per unit effort (CPUE) was calculated from the total catch in kg and the total effort.

Definitions of terms used

TERMS	DEFINITION
EEZ	Exclusive Economic Zone
WIO	Western Indian Ocean
NEI	Not elsewhere included
VESSELS LICENSED	Vessels licensed to fish in the Seychelles EEZ.
VESSELS COVERED	Vessels for which a logbook has been received containing at least one fishing day during the month; or a vessel that is not fishing yet the SFA knows of its activities.
FISHING DAYS	Days spent at sea minus days on passage, days adrift due to mechanical breakdown or other work stoppage. This may include days spent in searching even if no fish was caught or days spent drifting.
CATCH	MT - Metric Tonne (1000 kg)
CATCH RATE	Total Catch per fishing effort.
TRANSSHIPMENT	Generally, the transfer of tuna fish from a catcher vessel to a 'reefer' or cargo vessel. This normally takes place in port.
LANDING	This also includes fish landed in Port Victoria, Seychelles for the IOT canning factory. Most of this is subsequently re-exported.
COUNTRY OF REGISTRATION	Country in which ownership of the vessel is registered.
FLAG	Country and agreement under which the vessel is managed.

Purse Seine Fishery

1. SUMMARY OF PURSE SEINE FISHERY

1.1. Vessels Licensed and Active

- The number of purse seiners licensed to operate within the Seychelles Exclusive Economic Zone (EEZ) has shown notable fluctuations over the past decade. In 2016, a total of 49 vessels were licensed. However, a downward trend followed, with the number of licensed vessels declining to 44 by 2018. Since then, the trend has reversed, showing a gradual increase, reaching 50 licensed vessels in 2024, marking the highest number recorded during the period under review.(Table 1.2).

- In 2025, a total of 49 purse seiners were licensed to operate within the Seychelles EEZ, (Table 1.2A). Of these, 15 vessels were Seychelles-flagged, representing 31% of the total licensed fleet. The majority of the vessels (24 vessels or 49%)—were licensed under the Sustainable Fisheries Partnership Agreement (SFPA) with the European Union. Additionally, 3 vessels (6%) operated under a bilateral fishing agreement with Mauritius, while the remaining 10 vessels (20%) were licensed through private fishing agreements. It is worth noting that three vessels changed their flag from French to Omani, while two new vessels were added to the Seychelles fleet, bringing the total to 15 vessels, compared with 13 vessels in the previous years.

- The number of supply vessels licensed to operate within the Seychelles EEZ increased from 19 vessels in 2015 to a peak of 22 vessels in 2016. This level remained stable for three consecutive years before declining steadily, reaching a low of 12 licensed vessels in 2023. In 2024, an additional vessel was licensed to operate within the Seychelles EEZ, bringing the total number of licensed supply vessels to 13 that year.

- In 2025, the number of licensed supply vessels remained at 13 vessels. Of these, 6 vessels were licensed under the SFPA with the European Union, 4 vessels were Seychelles-flagged, and 3 operated under private fishing agreements.

- The total number of purse seiners active shows similar historical trend to the number of vessels licensed over the last 10 years (table 1.2B).

- In 2025, an average of 44 vessels were active per month, compared to 43 vessels in 2024 (Table 1.2C). Since 2017, there was a tendency for the number of active vessels to decrease in the final quarter of the year. This reduction is largely attributed to vessels ceasing operations after reaching their yellowfin tuna quotas. However, this trend was not evident during 2024 and 2025. During the last quarter of 2025, 45 vessels remained active, compared to 44 vessels active during the same period in 2024.

- In summary, the number of purse seiners licensed to operate in the Seychelles EEZ has varied over the past decade, with an initial increase followed by a decline and then a gradual recovery in recent years. Supply vessels showed a similar pattern, with numbers peaking mid-decade before declining, followed by a slight increase in 2024

and remaining stable in 2025. The number of active purse seiners generally mirrored licensing trends, with a slight increase in monthly averages compared to the previous year and no notable seasonal decline observed in number of vessel active during the final quarter of 2025 which has been the case since introduction of fishing quotas in Indian Ocean tuna fishery.

1.2. Fishing Effort, Catches and Catch Rate in WIO

- Analysis of the catch trends by purse seiners licensed to fish in Seychelles waters over the past decade shows a gradual increase from 289,704 MT in 2015, reaching a peak of 439,831 MT in 2018 (figure 1A). This peak was followed by a decline, with catches decreasing to 353,675 MT by 2020. In 2021, there was a significant rebound, with catches increasing by 17% to an estimated 412,922 MT. This was followed by a downward trend in catches, which declined to 373,123 MT in 2023 and remained relatively stable at 374,344 MT in 2024.

- Fishing effort, measured in terms of fishing days, showed an increasing trend from 12,756 fishing days in 2015 to a peak of 13,825 fishing days in 2016 (Figure 1B). Following this peak, fishing effort declined gradually, reaching a low of 9,579 fishing days in 2022. The fishing effort has since been on an increasing trend, reaching a total of 11,978 fishing days in 2024.

- The catch rate shows an increasing trend from 22.71 MT/fishing days in 2015 to reach 42.70 MT/fishing day in 2021 (table 1.3 and figure 1C). Since then, the catch rate has been on a declining trend, reaching 31.25 MT/fishing day in 2024.

- According to 100% logbook data received by the SFA, the total catch in the Western Indian Ocean (WIO) by purse seiners licensed to fish within the Seychelles EEZ for the year 2025 is estimated at 447,804 MT, representing a 20% increase compared with the 374,344 MT recorded in 2024 and marking the highest recorded catch over the past 20 years (table 1.3B). Despite this increase in catch, fishing effort decreased by 5%, from an estimated 11,978 fishing days in 2024 to 11,423 fishing days in 2025. Consequently, the mean catch rate increased from 31.25 MT/fishing day in 2024 to 39.20 MT/fishing day in 2025.

- During the first semester of 2025, purse seine tuna catches in the WIO were estimated at 203,204 MT, representing a 10% increase compared to the same period in 2024. This catch was achieved from a total fishing effort of 5,652 fishing days, resulting in a mean catch rate of 35.96 MT/ fishing day (Table 1.3). In contrast, the total catch for the first semester of 2024 was estimated at 185,269 MT, derived from higher fishing effort of 6,193 fishing days, hence with a lower mean catch rate of 29.92 MT/ fishing day.

- In the second semester of 2025, total purse seine tuna catches in the WIO were estimated at 244,599 MT, an increase of 29%, compared to the 189,075 MT recorded during the same period in 2024. This catch was achieved from a fishing effort of 5,771 fishing days, slightly lower than the 5,785 fishing days recorded in the second

semester of 2024. As a result, the catch rate improved from 32.68 MT/ fishing day in 2024 to 42.38 MT / fishing day in 2025.

In summary, over the past decade, purse seine catches in Seychelles waters have fluctuated, peaking in 2018 before declining to a low in 2020 and subsequently fluctuating. Fishing effort followed a similar trend, increasing until 2016 before gradually decreasing, with a slight recovery in 2024. Catch rates improved significantly up to 2021 but declined thereafter until 2024. In 2025, total catch increased to the highest recorded level over the past 20 years, despite a slight reduction in fishing effort, resulting in a higher average catch rate. Semester analysis shows that both semesters of 2025 recorded higher catches and catch rates compared with 2024.

1.2.1. Fishing Effort, Catches and Catch Rate in WIO by Fleet

- In 2025, the Spanish fleet continued to dominate the purse seine catches in the WIO, accounting for 33% of the total catch. This represents a slight increase from the previous year, where the Spanish fleet accounted for 32% of the total catch. The Seychelles fleet followed, contributing 30% of the total catch, a slight decrease from 31% reported in 2024. The French fleet accounted for 19% and 15% of the total catch, for the years 2024 and 2025 respectively. Additionally, vessels operating under private agreements made up 22% of the total catches in 2025 highlighting the growing contributions of vessels operating under private agreement over the last 2 years.

- In 2025, the Spanish fleet recorded a total catch of 147,005 MT, representing a 24% increase from an estimated catch of 118,572 MT caught in the previous year. This increase corresponded to a slight 1% reduction in fishing effort, with the fleet spending 3,378 days at sea fishing. Consequently, the catch rate for the Spanish fleet increase to 43.52 MT/fishing day in 2025, from 34.70 MT/fishing day in 2024.

- The Seychelles fleet reported an estimated catch of 134,240 MT in 2025, 16% higher than 115,488 MT reported in 2024. Fishing effort decreases by 5%, from 3,630 fishing days in 2024 to 3,460 fishing days in 2025. As a result, catch rate increased from 31.82 MT/ fishing day in 2024 to 38.80 MT/ fishing day in 2025. (Table 1.3B).

- The total catch for the French fleet in 2025 is estimated at 66,822 MT, representing an 8% reduction from 72,610 MT in 2024(Table 1.3D). This drop corresponds to a 33% decrease in fishing effort, from 2,832 fishing days in 2024 to 1,896 fishing days in 2025. The catch rate for the French fleet increased from 25.63 MT/ fishing day in 2024 to 35.25 MT/ fishing day in 2025.

- Vessels flagged under Mauritius, Italy, South Korea, Tanzania, Kenya, and Oman collectively reported a total catch of 99,737 MT in 2025, a 47% increase from 67,673 MT in 2024 (Table 1.3E). Fishing effort also increases by 28%, from 2,099 to 2,690 fishing days which may be attributed to the increase in number of vessels licensed in 2025. The average catch rate for these fleets increased slightly from 32.24 MT/ fishing day in 2024 to 37.08 MT/ fishing day in 2025.

- In summary, increases in both total catch and catch rates was observed for the Spanish and Seychelles fleets, despite reduction in fishing effort for both fleet in 2025. In contrast, the French fleet observed a decreases in both total catch and fishing effort, with an increase in catch rate. Vessels flagged under Mauritius, Italy, South Korea, Tanzania, Kenya, and Oman collectively recorded higher catches, fishing effort and catch rate.

1.3. Species Composition of Catches in WIO

- Figure 1J illustrates the trends in species composition by purse seiners licensed to fish within the Seychelles EEZ. Historically, skipjack tuna has been the dominant species in the purse seine catches in the WIO (see table 1.3). However, from 2012 to 2015, yellowfin tuna overtook skipjack as the most commonly caught species. Following the implementation of the yellowfin quota in the Indian Ocean in 2017, the purse seine tuna fishery has shifted back to primarily targeting skipjack tuna.

- During the year 2025, skipjack tuna remained the dominant species in the purse seine fishery, comprising 62% of the total catch. Yellowfin tuna followed, accounting for 29%, while bigeye tuna represented only 7% of the total catch. This species composition closely mirrors that of the previous year, when skipjack, yellowfin, and bigeye tuna accounted for 61%, 31%, and 6% of the total catch, respectively.

- In 2025, skipjack tuna catches increased by 21% from 227,772 MT in 2024 to an estimated total catch of 278,112 MT. The total yellowfin catches were estimated at 128,199 MT, 10% higher than the 116,137 MT reported for the previous year. Bigeye tuna catches increased by 34%, from 22,940 MT in 2024 to 31,165 MT in 2025.

- In summary Species composition in purse seine catches in Western Indian Ocean has historically been dominated by skipjack tuna, except for a brief period when yellowfin tuna was most prevalent. Since the introduction of yellowfin quotas in 2017, the fishery has shifted back to primarily targeting skipjack. In 2025, skipjack remained the dominant species, followed by yellowfin, while bigeye tuna contributed only a small share. Compared to the previous year, catches increase for all three main target species , skipjack yellowfin and bigeye.

1.4. Catch by School Type

- Trend analysis of the catch by school type, over the last 10 years shows that purse seiners licensed to fish inside the Seychelles EEZ reported to have fished more on FAD's associated school which accounted for an average of 84% of the total catches per year (table 1.5A and figure 1G).

- In 2025, an estimated 395,776 MT of tuna, representing 88% of the total purse seine catches were caught on fish aggregating device (FAD) associated schools, while 52,028 MT (12%) were caught on free-swimming schools. This marks a shift from the previous year, when 76% of the catch (284,981 MT) was taken from FAD-associated schools and only 24% (89,346 MT) from free-swimming schools. The data reflects an 39% increase

in catches from FAD-associated schools and a 42% decrease in catches from free-swimming schools.

- In 2025, skipjack tuna dominated catches from FAD-associated schools, accounting for 68% of the total, followed by yellowfin tuna at 23% and bigeye tuna at 7%. This composition is similar to 2024, when skipjack made up 68%, yellowfin 23%, and bigeye 6% of the FAD-associated catch. For free-swimming schools, yellowfin tuna remained the predominant species in 2025, representing 71% of the total catch, while skipjack and bigeye tuna accounted for 20% and 5%, respectively. In comparison, the 2024 catch from free-swimming schools comprised of 56% yellowfin, 38% skipjack, and 5% bigeye tuna.

- In summary, over the past decade, purse seiners operating in the Seychelles EEZ have predominantly targeted fish aggregating device (FAD)-associated schools, which consistently account for the majority of catches.. Skipjack tuna continued to dominate FAD-associated catches, followed by yellowfin and bigeye tuna, whereas yellowfin remained the leading species in free-swimming schools.

1.5. Activity inside the Seychelles EEZ

- An analysis of the purse seine fishery trends within the Seychelles EEZ over the past decade reveals a significant upward trend. Starting from an estimated catch of 49,046 MT in 2015, the catch volume oscillated upward, reaching a peak of 95,668 MT in 2020. However, this peak was followed by a sharp 56% decline in 2021, with catches dropping to 42,082 MT. Remarkably, in 2022, the purse seine fishery in the Seychelles EEZ experienced an extraordinary rebound, with catches increasing to a record 113,566 MT corresponding to an increase of 88% in fishing effort. This represents a remarkable 170% increase from the previous year's total. This catch volume is the highest reported within the Seychelles EEZ over the past 20 years, highlighting a significant statistic for the fishery. In 2023, a 39% decrease was reported in total catch resulting in an estimated catch of 69,261 MT. This was followed by 35% increase to reach a total catch of 93,329 MT in 2024.(figure 1D).

- Fishing effort in the Seychelles EEZ showed a steady decline from 4,740 fishing days in 2016 reaching a low of 1,579 fishing days in 2021. Since then, the effort rebounded, to reach a total of 3,959 fishing days in 2024. (Figure 1E). Catch per unit effort exhibited a fluctuating trend rising from 16.34 MT/fishing day in 2015, to 33.00 MT/fishing day in 2019. A subsequent decline brought the catch rate down to 26.84 MT/fishing day in 2021, before surging to a record high of 38.22 MT/fishing day in 2022, the highest recorded in the Seychelles EEZ over the past decades. The catch rate has since been on a decreasing trend to reach 23.57 MT/fishing day in 2024.(Figure 1F).

- In 2025, the total catch inside of the Seychelles EEZ was estimated to be 79,798 MT, representing a decrease of 14% from 93,329 MT reported for the year 2024. The decrease in catches corresponds to a decrease of 34% in fishing effort from 3,959 fishing day in 2024 to 2,603 fishing days in 2025. The mean catch rate for 2025 within

the Seychelles EEZ was 30.66 MT/ fishing day, from the 23.57 MT/fishing day recorded in 2024 (table 1.4).

- During the first semester of 2024, purse seine tuna catches reported within the Seychelles EEZ were estimated at 55,457 MT, achieved from a fishing effort of 1,722 fishing days. This yielded a mean catch rate of 32.21 MT/ fishing day. This reflects a 28% increased from a total reported catch of 43,182 MT, during the same period , the previous year, despite a 14% reduction in fishing effort from 1,993 fishing days. Hence catch rate increased significantly from 21.67 MT/ fishing day to 32.21 MT/ fishing day (table 1.4A).

- In contrast, the second semester of 2025 saw a substantial decrease in both total catch and fishing effort. A total of 24,340 MT of tuna was reported, obtained from 881 fishing days. This represents a 51% decrease in total catch compared to the 50,147 MT recorded during the same period in 2024, which was achieved from a fishing effort of 1,967 fishing days. The catch rate increased slightly, from 25.50 MT/ fishing day in 2024 to 27.62 MT/ fishing day in 2025.

- During 2025, the highest monthly tuna catches and catch rate by purse seiners within the Seychelles EEZ was recorded in February, with an estimated 24,057 MT and 44.51 MT/fishing days. In contrast, the peak catch in 2024 were both observed in August, with a total catch of 17,399 MT. However, the highest catch rate for that year occurred in July, reaching 33.32 MT/fishing day.

- In summary, over the past decade, purse seine catches within the Seychelles EEZ have shown significant variability, with periods of sharp increases and declines. After reaching a peak in 2020, catches dropped substantially in 2021 before rebounding to a record high in 2022, followed by another decline in 2023 and a notable recovery in 2024. Fishing effort mirrored these fluctuations, while catch rates have varied, reaching historic highs in 2022 before declining in subsequent years. In 2025, catches and fishing effort decreased, resulting in an increase in the catch rate.

1.5.1. Activity inside the Seychelles EEZ by Foreign Fleet

- During the year 2025, the Spanish and Seychelles fleet, each accounted for 29% of the total catches in the Seychelles EEZ. In 2024, Spanish fleet accounted for 31% of catches while Seychelles fleet accounted 24%. The French Fleet accounted for 19% of the Seychelles EEZ catches in 2025 compared to 28% during the previous year.

- In 2025, the Spanish fleet reported an estimated catch of 22,776 MT within the Seychelles EEZ, representing a 21% decrease compared to the 28,678 MT recorded in 2024. This decline in catches was associated with a reduction ogf 40% in fishing effort whilst the mean catch rate increased from 26.65 MT/ fishing day in 2024 to 35.00 MT/ fishing day in 2025 (table 1.4C).

- The French fleet reported a total catch of 15,479 MT inside the Seychelles EEZ achieved from a total effort of 5,29 fishing days during the year 2025, (table 1.4 D). This

represents a 41 % decrease in catches corresponding to a 55% reduction in fishing effort inside the Seychelles EEZ thus giving mean catch rate of 29.23 MT/fishing day compared to 22.22 MT/fishing day estimated for the previous year.

- In summary, fleet contributions to purse seine catches within the Seychelles EEZ in 2025 showed both Seychelles and Spanish fleets as the largest contributors, followed by the French fleet. Compared to the previous year, the Spanish fleet recorded lower catches due to reduced fishing effort, resulting in higher catch rate. Similarly, the French fleet reported a significant decline in catches, as a result of a substantial reduction in effort, however its catch rate increased relative to the previous year.

1.6. Statistics of Seychelles Flagged Vessels

- Trend analysis of the Seychelles flagged purse seine catches over the last 10 years shows an overall increasing trend. Total Catches increase from 88,740 MT in 2015 to reach a peak of 123,310 MT in 2018 and has subsequently fluctuated at relativbely high levels, averaging 117,511Mt anually over the last 6 years. The fishing effort has increased from 3,264 fishing days in 2015 to reach a peak of 4,092 fishing days in 2016. followed by s decline through 2018 and subsequent fluctuations between 2,922 to 3,727 fishing days. The mean catch rate varied between 26.55 MT/ fishing day and 44.25 MT/ fishing day between 2015 to 2018 and have averaged 36.57 MT/ fishing day over the past 5 years.

- In 2025, Seychelles-flagged purse seiners reported a total catch of 134,240 MT in the WIO, the highestannual catch recorded over the past 20 years, achieved from 3,460 fishing days. This represents a 16% increase in total catch despite a 5% reduction in fishing effort compared to 2024, when the fleet recorded a total catch of 115,488 MT over 3,630 fishing days. Consequently, the mean catch rate increases, from 31.82 MT/ fishing day in 2024 to 38.80 MT/ fishing day in 2025 (table 1.3B). The higher catches may be attributed to the increase in the number of licensed vessels opearting in 2025.

- Catches by the Seychelles purse seine fleet inside the Seychelles EEZ were estimated at 23,334 MT in 2025 compared with 22,720 MT during the previous year. This represents a slight 3% increase in catches despite a 24% reduction in fishing effort (table 1.4B). As a result, the mean catch rate for the Seychelles fleet inside the Seychelles EEZ increased to an estimated 30.75 MT/ fishing day in 2025, compared to 22.76 MT/ fishing day in 2024 (table 1.4B).

- In 2025, the Seychelles purse seine fleet reported that 73% of their total catches were taken on the high seas, while 17% were caught within the Seychelles EEZ. The remaining 10% of the catches originated from the EEZs of other countries. During the previous year, 50% of the Seychelles fleet's catches were made on the high seas, and 20% were caught within the Seychelles EEZ.

- In summary, over the past decade, Seychelles-flagged purse seine catches have generally increased, reaching a record level in 2025, despite a slight reduction in fishing effort, resulting in a higher average catch rate, compared to the previous year. Inside

the Seychelles EEZ, catches increase slightly while fishing effort declined substantially. with a larger proportion of catches taken on the high seas and a reduced share originating from within the Seychelles EEZ relative to the previous year.

1.7. Purse seine statistics by Access Regime

- In 2025, purse seiners licensed to operate inside of the Seychelles EEZ were operating under the National or Seychelles flag licences, Sustainable Fisheries Partnership Agreement between the European Union (EU) and the Seychelles hereafter referred to as the SFPA agreement, Seychelles Mauritius Bilateral and under private agreement with South Korea, Oman, Kenya and Tanzania hereafter group as 'Others'.

- In 2025, vessels operating under the SFPA agreement reported a total catch of 40,775 MT within the Seychelles EEZ, accounting for 51% of the total reported catch in this area. This represents a 29% decrease from the 57,289 MT reported in 2024. The fishing effort for these vessels in 2025 amounted to 1,246 fishing days, resulting in a mean catch rate of 32.73 MT/ fishing day. In comparison, a higher fishing effort of 2,373 fishing days were reported during the previous year, with a mean catch rate of 24.14 MT/fishing day (table 1.6).

- Vessels operating under other agreements reported a total catch of 15,688 MT within the Seychelles EEZ in 2025. This represents an 18% increase compared to the previous year's catch of 13,320 MT. There was a slight 2% increase in fishing effort, with 598 fishing days in 2025 compared to 588 fishing days in 2024. Consequently, the mean catch rate for these vessels recorded a slight increase, from 22.65 MT/ fishing day in 2024 to 26.22 MT/fishing day in 2025. Vessels under other agreements accounted for only 20% of the total catch in the Seychelles EEZ in 2025.

- In summary, Vessels under the SFPA accounted for the majority of catches, showing a decrease compared to the previous year, achieved from lower fishing effort though with an increase in catch rate. On the contrary, vessels operating under private agreements, observed an increase in both fishing effort and catches.

1.8. Landing and Transhipment Statistics

Starting in 2023, catches unloaded at the Central Common Cold Store (CCCS) have been classified as landings rather than transshipments, despite most being destined for export. This change reflects CCCS's dual role in supporting both export and local processing. Consequently, figures in this report may differ from previously published data due to this updated classification.

The landing and transhipment data presented in this report relate exclusively to the period during which the vessel held a valid licence to fish within the Seychelles Exclusive Economic Zone (EEZ). Any landings or transhipments conducted at Port Victoria outside the vessel's licensed fishing period may originate from fishing activities undertaken outside the Seychelles EEZ and are therefore not covered by this report. Consequently, the data should not be interpreted as representing the vessel's total landings or

transhipments at Port Victoria, but only those attributable to operations conducted under a valid Seychelles fishing licence within the corresponding licence period.

- Time series analysis of landing and transhipment in Port Victoria shows an increasing trend from 269,087 MT in 2015 to reach a peak of 426,981 MT in 2018, which was then followed by a decreasing trend to reach 336,384 MT in 2020 (table 1.7 and figure 1K). Landing and transhipment increased by 16 % to reach a total of 389,542 MT in 2021, followed by a 15% decrease to reach a total of 331,261MT of tuna unloaded through port Victoria, in 2024.

- As in previous years, Port Victoria remained the principal port for tuna transhipment and landing by purse seiners in the WIO during the year 2025. A total of 412,076 MT of tuna was unloaded through port Victoria compared to 331,261 MT in 2024 representing a 24% increase. This volume accounted for 94% of the total landing and transhipment for that year (figure 1L).

- In the year 2025, a total catch of 312,555 MT, represneting 76% of total purse seine catches unloaded in Port Victoria was transhipped onto reefers or into containers for export whilst the remaining 98,724 MT (24%) was landed in Port Victoria for local processing, sale or storage at CCCS (table 1.9). In comparison, 240,763 MT of tuna were transhipped and 88,569MT were landed in Port Victoria in 2024. This represent a increase of 30% in transhipment and 11% in landings in port Victoria respectively during the year 2025 when compared to the previous year excluding discards.

- In 2025, Indian Ocean Tuna Ltd (IOT) accounted for 64% of total landings at Port Victoria, while CCCS, and other local companies accounted for 23% and 13%, respectively. The majority of landings comprised tuna and tuna-like species (88%), with the remaining 12% consisting of bycatch. Landings at IOT increased by 13% , from 55,496 MT in 2024 to 62,922 MT in 2025. Landing at CCCS, remained stable at to 23,068 MT in 2025, compared to 23,136 MT recorded in the previous year. Catches sold to other local companies increased by 28%, consisting predominantly of bycatch species(Table 1.9).

- Out of the 312,555 MT of tuna transhipped in Port Victoria, 124,419 MT (40%) was transhipped onto reefer vessels whilst 188,136 MT (60%) was transhipped into containers for export excluding discards (table 1.9). This represents a 20% increase in tuna transhipped via containers and an increase 48% of tuna transhipped via reefer vessels respectively when compared to the previous year. In 2024 a total of 84,212 MT or 35% of total tuna transhipped were by reefer vessels and 65% or 156,551 MT of tuna were transhipped into containers excluding discards. The substantial increase in reefer transhipments is largely attributed to constraints in the availability of refrigerated shipping containers in Port Victoria, resulting in greater reliance on conventional reefer carriers for frozen fish exports

- Analysis of catch unloaded in port Victoria by fleet shows that historically, the Spanish fleet dominated tuna unloading in Port Victoria. In 2025 the Spanish fleet landed and

transhipped a total of 135,506 MT of tuna in port Victoria representing 33% of the total catch unloaded in Port Victoria during that year whilst the French and Seychelles fleet accounted for 13% (or 53,202 MT) and 31% (or 127,539 MT) respectively (table 1.8). During the previous year, the Spanish fleet accounted for 35% (or 115,982MT) of landing and transhipment in Port Victoria whilst the French and Seychelles fleet accounted for 18% (or 60,729 MT) and 34% (or 113,614 MT) respectively.

- Bycatch and discards combined made up of around 3% of the total volume unloaded in Port Victoria in both 2024 and 2025. The estimated bycatch unloaded in Port Victoria was 12,172 MT in 2025 and 7,334 MT in 2024, while discards declined from 1,928 MT to 797 MT in 2025. *Readers should be aware that in previous years, bycatch may have been reported under "Mixed species" along with tuna species not classified elsewhere*.

- In summary, in 2025, Port Victoria remained the primary hub for tuna unloading in the WIO, with the majority of catches transhipped for export and a smaller share landed for local processing and storage. Both landings and transhipment increased during the year, driven by higher volumes landed at IOT and growing sales to local companies. Transhipment activity continued to be dominated by containerized exports rather than reefer vessels. Fleet contributions remained dominated by the Spanish fleet, followed by Seychelles-flagged and French vessels.

1.9. Fishing Ground

- Map 1A and 1B show the distribution of reported catch of purse seiner by 1º square in the WIO for the years 2024 and 2025 respectively. Map 1C and 1D shows the distribution of reported catch of purse seiner by 1º square in the WIO for the 1st Semester of 2024 and 2025 respectively whilst maps 1E and 1F show the distribution of reported catch of purse seiner by 1º square in the WIO for the 2nd Semester of 2024 and 2025 respectively.

- Comparison of Maps 1A and 1B indicates a shift in the spatial distribution of purse seine catches in 2025 relative to 2024. Lower catch concentrations were observed in the Mozambique Channel and the NW Seychelles region, while higher catches were recorded in the SE Seychelles area and the Arabian Sea. (Map 1B).

- Maps 1D shows lower catch concentrations in the Mozambique Channel and reduced catches in skipjack tuna in NW Seychelles area. In contrast higher catch concentrations were observed in the SE Seychelles during the first semester of 2025 when compared to the same period in 2024 (Map 1C).

- Maps 1F shows an increased skipjack tuna catches in E.Somalia and in the Arabian Sea while catches of yellowfin tuna declined in both the NW and SE Seychelles. In addition catches of all major species decreased in the Mozambique Channel area during the second semester of 2025 when compared to the same period in 2024 (map 1E).

- In summary, the spatial distribution of purse seiner catches in the WIO during 2025

showed a notable shift in fishing activity compared with 2024. Overall catch concentrations decreased in the Mozambique Channel and NW Seychelles, while increasing in SE Seychelles and the Arabian Sea. During the second semester, skipjack catches increased in eastern Somalia and the Arabian Sea, while yellowfin catches declined in the Seychelles areas and catches of all species decreased in the Mozambique Channel. These changes suggest a redistribution of fishing activity towards the northern area of the western Indian Ocean, potentially reflecting changes in environmental conditions, tuna availability, and fleet operational strategies.

Industrial Longline Fishery

2. SUMMARY OF INDUSTRIAL LONGLINE FISHERY

2.1. Logbook Returned

- The statistics published for the year 2025 and 2024 are based on 100% of logbooks captured in the database at the time the statistical tables (Table 2.2) were generated.

2.2. Vessels Licensed and Active

- The number of industrial longliners licensed to operate within the Seychelles EEZ increased from 155 vessels in 2015 to 213 vessels in 2017, before declining to 162 vessels licensed in 2020. Although the number of licensed vessels increased by 16% in 2021, it subsequently followed a declining trend reaching a 10-year low of 86 vessels licensed in 2024. (table 2.1).

- In 2025, the number of vessels licensed to fish within the Seychelles EEZ increased by 14 vessels, reaching a total of 100 licensed vessels compared to 86 in 2024. The number of Seychelles-registered vessels increased by 52%, from 27 vessels in 2024 to 41 vessels in 2025. In contrast, the number of licensed vessels flagged under Taiwan Province of China decreased by 9%. Two vessels operating under the Oman flag were licensed in 2025, compared to three vessels in 2024. Under the China Overseas Fisheries Association (COFA) agreement, 14 Chinese-flagged longliners were licensed in 2025. No vessels were licensed under either the EU Agreement or the Mauritius bilateral agreement in 2025.

- On average, 34 Seychelles registered longliners were active per month during the year 2025 compared to 22 vessels active during the previous year. In 2025, the average number of Taiwanese vessels remain stable around 21 vessels active per month. It is worth noting that the Chinese flagged longliners obtained their licenses to fishing inside Seychelles EEZ in October 2025 and were therefore active only during the last quarter of the year. (table 2.1C).

- After reaching a 10-year low of 86 licensed industrial longliners in 2024, the number of vessels licensed to operate in the Seychelles EEZ increased to 100 in 2025. The growth was driven mainly by a 52% increase in Seychelles-registered vessels, while the number of vessels flagged under Taiwan Province of China and Oman declined slightly. Fourteen Chinese-flagged longliners were licensed under the COFA agreement after no licences were issued in 2023 and 2024, while no vessels were licensed under the EU or Mauritius agreements. Vessel activity also increased, particularly among Seychelles-registered longliners.

2.3. Fishing Effort, Catches and Catch Rate in WIO

- From 2015 to 2020, the total catch in WIO by vessel licensed to fish inside the Seychelles EEZ, showed an increasing trend, rising from 20,396 MT to a peak of 31,496 MT in 2020, before declining to 18,119 MT in 2023. This was followed by a 15%

increase to a total catch of 20,836 MT in 2024. A similar trend was observed in fishing effort over the same period. The catch rate declined from 0.52 MT/1000 hooks in 2015 to 0.38 MT/1000 hooks in 2017, then increased to 0.56 MT/1000 hooks in 2019, before decreasing again to 0.37 MT/1000 hooks in 2022. Subsequently, the catch rate rebounded, reaching 0.59 MT per 1,000 hooks in 2024 (Figure 2C).

- The total catch reported by all industrial longline fleet licensed to fish in the Seychelles EEZ during year 2025 was estimated at 21,695 MT, obtained from a fishing effort of approximately 44.4 million hooks thus giving a mean catch rate of 0.49 MT/1000 hooks (table 2.2A). In comparison, the total catch for the previous year was estimated at 20,836 MT, with a fishing effort of approximately 35.2 million hooks and a mean catch rate of 0.59 MT/1000 hooks. This indicates a 5% increase in total catch in 2025 corresponding to a 26% increase in fishing effort.

- During the first semester of 2025, the industrial longline fleet in the WIO reported a total catch of 10,218 MT, representing a 17% increase compared to 8,766 MT during the same period in 2024. This catch was achieved with an estimated fishing effort of 18.5 million hooks, resulting in a mean catch rate of 0.55 MT/1000 hooks (Table 2.2A). This reflects a 23% increase in fishing effort compared to the previous year, when approximately 15.1 million hooks were deployed, yielding a mean catch rate of 0.58 MT/1000 hooks.

- During the second semester of 2025, the reported total catch was 11,476 MT, obtained from a fishing effort of 25.9 million hooks. This represents a reduction of 5% compared to the 12,070 MT recorded during the same period in 2024. Over the same period, fishing effort increased from approximately 20.1 million hooks in 2024 to 25.9 million hooks in 2025 . Consequently the mean catch rate declined from 0.60 MT/1000 hooks in the second semester of 2024 to 0.44 MT/1000 hooks in the corresponding period of 2025.

- A monthly analysis of catch rates indicates that the highest catch rate in 2025 was recorded in April, at 0.68 MT/1000 hooks. In contrast, the highest catch rate in 2024 was 0.79 MT/1000 hooks, recorded in May.

- In summary, Industrial longline catches in the WIO have fluctuated over the past decade. In 2025, both total catch and fishing effort increased, resulting in lower catch rates compared to the previous year. Semester analysis indicates higher catch rate in the first half of the year, while monthly trends show peak performance occurring mid-year.

2.3.1. Fishing Effort, Catches and Catch Rate in WIO by Fleet

- The Seychelles fleet reported an estimated catch of 14,768 MT for the year 2025, achieved from a fishing effort of 29.0 million hooks, resulting in a mean catch rate of 0.51 MT/1000 hooks (Table 2.2C). This reflects a 27% increase in catches corresponding to a 48% increase in fishing effort when compared to the previous year mainly attributed to the increase in number of vessels. In 2024, the Seychelles fleet recorded

a total catch of 11,606 MT from a fishing effort of 19.6 million hooks, with a mean catch rate of 0.59 MT/1000 hooks.

- The total catches reported by the Taiwanese fleet for the year 2025 is estimated at 5,624 MT, achieved from a fishing effort of 12.1 million hooks resulting in a mean catch rate of 0.46 MT/1000 hooks. This represents a 20% and 3% reduction in catches and fishing effort, respectively when compared to the previous year. In 2024, the Taiwanese fleet reported a total catch of 7,060 MT achieved from a fishing effort of 12.6 million hooks, yielding a mean catch rate of 0.56 MT/1000 hooks (Table 2.2D).

- The Chinese and Omani fleets accounted for the remaining 1,303 MT of tuna and tuna-like species reported in the industrial longline fishery in 2025. This catch was achieved with an approximate fishing effort of 3.2 million hooks, resulting in a mean catch rate of 0.41 MT/1000 hooks. In comparison the Mauritian and Omani fleets reported an estimated catch of 2,170 MT, from a similar fishing effort of approximately 3.0 million hooks, corresponding to a substantially higher mean catch rate of 0.72 MT/1000 hooks (Table 2.2E).

- In summary, in 2025, the Seychelles fleet recorded higher catches and fishing effort, resulting in lower catch rates compared to the previous year whilst the Taiwanese fleet reported lower catches and effort, with a decrease in catch rate. Omani and Chinese fleets contributed a smaller share of the total catches but showed decrease in both catches and catch rates compared to Omani and Mauritian fleets in 2024.

2.4. Species Composition in WIO

- Historically bigeye dominated the catch of the industrial longline fishery with exception for the year 2018 to 2019 and in 2024 where yellowfin tuna replaced bigeye tuna as the dominant species caught the industrial longline fleet (table 2.2B).

- In 2025, bigeye tuna was the dominant species, accounting for 44% of the total catch, whilst yellowfin tuna, swordfish, and the "others" category represented 30%, 6%, and 14%, respectively. In 2024, the total catch consisted of 40% yellowfin tuna ,followed by 39% bigeye tuna, with the "others" category making up 10% of the total catch. Notably, the "others" category comprised 34% each for Ruvettus pretiosus (oilfish) and albacore in 2025, while these two species accounted for 43% and 22% of total catches of the "others" category in 2024, respectively.

- In 2025, catches of marlin, ‘other’ category, swordfish and bigeye tuna increased by 77%, 39%, 20%, and 17% respectively. In contrast catches of yellowfin tuna and sharks declined by 22% and 21%, respectively compared to the previous year.

- In summary, bigeye tuna has historically been the dominant species in industrial longline catches, except for a brief period when yellowfin tuna accounted for the largest share of the catch. In 2025, bigeye tuna remained the principal species, followed by yellowfin tuna, while swordfish and species grouped under the “others” category contributed smaller proportions of the total catch. The “others” category was

largely composed of oilfish (Ruvettus pretiosus) and albacore tuna, each accounting for 34% of catches within the category. Compared to 2024, catches of marlin, species in the "others" category, swordfish, and bigeye tuna increased, whereas catches of yellowfin tuna and sharks declined, resulting in a noticeable shift in the overall catch composition.

2.5. Activity inside the Seychelles EEZ

- Time series of total catch and fishing effort of industrial longliners inside the Seychelles EEZ shows similar trend to that in the WIO. Total catches peaked at a record 15,626 MT in 2016 before declining through 2019. Catches then stabilised, averaging approximately 14,644 MT during 2020 and 2021, before entering another downward trend that resulted in a low of 10,580 MT in 2023.. However, a 42% increase was observed in 2024, bringing the total catch to 14,229 MT.(Table 2.3, Figures 2D, 2E, and 2F).

- According to logbooks received and recorded by the SFA, an estimated catch of 12,650 MT was reported inside the Seychelles EEZ by industrial longliners in 2025. This represents a 16% reduction in catches, despite a 14% increase in fishing effort compared with the previous year. The estimated fishing effort for the year 2025 was approximately 26.5 million hooks, resulting in a mean catch rate of 0.48 MT/1000 hooks (Table 2.3A). In contrast, a total catch of 14,992 MT obtained from a fishing effort of approximately 23.2 million hooks was reported for the year 2024, resulting in a mean catch rate of 0.65 MT/1000 hooks.

- During the first semester of 2025, industrial longliners reported an estimated catch of 4,403 MT inside the Seychelles EEZ, achieved from a fishing effort of approximately 8.1 million hooks, resulting in a mean catch rate of 0.55 MT/1000 hooks. This represents a drop of 26% and 9% in catches and effort respectively compared to the same period in the previous year, when catches were estimated at 5,964 MT from approximately 8.9 million hooks, yielding a mean catch rate of 0.67 MT/1000 hooks.

- During the second semester of 2025, a total of 8,247 MT of tuna was reported to have been caught by industrial longliners inside the Seychelles EEZ achieved from a fishing effort of approximately 18.4 million hooks, resulting in a mean catch rate of 0.45 MT/ 1000 hooks. This reflects a 9% reduction in total catch compared to 9,029 MT reported during the second semester of 2024, despite a substantial increase of 29% in fishing effort.

- Analysis of monthly trend in 2025 shows higher catches were recorded inside the Seychelles EEZ during the month of December of the year similar to previous year .

- Industrial longline catches within the Seychelles EEZ have generally followed the same pattern as those in the Western Indian Ocean, with periods of growth, decline, and recovery over the past decade. Although catches rebounded in 2024, lower catches were reported in 2025 despite increased fishing effort resulting in declined in catch

rates. Both the first and second semesters recorded lower catches than the corresponding periods in 2024.

2.6. Statistics of Seychelles Flagged Vessels

- An increasing trend has been observed in total catch by Seychelles registered industrial longliners from the year 2015 to reach a peak of 22,866 MT in 2019 (table 2.4 and figure 2G). This was followed by a decreasing trend to reach a total of 9,627 MT in 2023. Catches increase by 21% to reach a total of 11,606 MT in 2024. A similar trend was noted in fishing effort, which increased from 22.8 million hooks in 2015 to 40.6 million hooks in 2020, subsequently decreasing to 19.6 million hooks in 2024 (Table 2.4 and Figure 2H). The catch rate fluctuated between 0.59 MT/1000 hooks and 0.36 MT/1000 hooks from 2015 to 2024 (Figure 2I).

- During the year 2025, the Seychelles fleet reported an estimated catch of 14,768 MT representing an increase of 27% in catches with a corresponding 48% increase in fishing effort. This was achieved from a fishing effort of 29 million hooks and a mean catch rate of 0.51 MT/1000 hooks (table 2.2C). During the previous year, the Seychelles fleet reported a total catch of 11,606 MT achieved from a fishing effort of 19.6 million hooks with a mean catch rate of 0.59 MT/1000 hooks.

- The Seychelles flagged industrial longliners reported to have caught 56% of their total catch on the high Seas and 44% in the Seychelles EEZ during the year 2025. During the previous year, 47% and 53% of the Seychelles flagged industrial longliners catches were caught on the high Seas and inside Seychelles EEZ, respectively.

- In summary, Seychelles-flagged industrial longliners recorded an overall increase in catches up to 2019, followed by a decline until 2023 and a moderate increase from 2024 onwards. Fishing effort followed a similar pattern, while catch rates fluctuated over the years. In 2025, both catches and fishing effort increased, resulting in higher catch rates. Spatial distribution shifted notably, with a larger proportion of catches occurring inside the high seas compared to the previous year.

2.7. Industrial Longliners statistics by Access Regime

- During the years 2025 and 2024, industrial longliners licensed to operate inside of the Seychelles EEZ were operating under the two main fishing agreements: the Taiwan Deep-sea Tuna Longline Boat Owners and Exporters Association (TTA) and Deep Sea (National) Agreement. Few vessels were also operating under the Top Fortune International (TFI) agreement, Seychelles - Mauritius Bilateral agreement and China Overseas Fisheries Association (COFA) agreement.

  For year 2025, vessels operating under the National agreement accounted for 51% of the total EEZ catch whilst vessels operating under the TTA agreement represent 37% of the total EEZ catch. During 2024, vessels operating under the National agreement accounted for 41% of the total EEZ catch whilst vessels operating under the TTA agreement represented 44% of the total EEZ catch.

2.8. Fishing Ground

- Map 2A and 2B show the distribution of reported catch of industrial longliners by 1º square in the WIO for the years 2024 and 2025, respectively. Map 2C and 2D shows the distribution of reported catch of industrial longliners by 1º square in the WIO for the 1st Semester of 2024 and 2025 respectively whilst maps 2E and 2F shows the distribution of reported catch of industrial longliners by 1º square in the WIO for the 2nd Semester of 2024 and 2025, respectively.

- Maps 2B shows similar fishing spatial distribution of industrial longliners catches in 2024 and 2025 (map 2A). However notable differences in species composition are evident. In 2025 yellowfin tuna catches were less prominent in Indian Ocean Monsoon Gyre area while an increase in other species category catches, particularly albacore tuna in South tropical convergency area was observed.

- Map 2D shows an increase in catches of bigeye tuna , with a decrease yellowfin in the Indian Ocean Monsoon Gyre area . An increase in catches of other species category, particularly albacore tuna in South tropical convergency area during the first semester of the year 2025 when compared to the same period in 2024 (Map 2C).

- Comparing maps of catches for semester 2 of year 2025 (Map 2F) with the same period for the previous year revealed an increase in catches in the North West area of Seychelles with an increase in catches of 'Other' species in southern Indian Ocean area

- The spatial distribution of industrial longline catches remained broadly consistent between the two periods, with fishing activity concentrated in the western equatorial Indian Ocean, particularly in and around the Seychelles region. Secondary fishing grounds were observed in the central Indian Ocean and, to a lesser extent, in the southern Indian Ocean. While the geographic distribution of fishing activity changed little, notable shifts occurred in species composition, with increased catches of bigeye tuna within the main fishing grounds and greater catches of albacore and other species in the South Tropical Convergence Zone. Conversely, the relative contribution of yellowfin tuna was lower, particularly in the Indian Ocean Monsoon Gyre area. Overall, the maps indicate stable fishing grounds but changes in the composition of catches across key fishing areas.

Semi-Industrial Longline Fishery

3. SUMMARY OF SEMI INDUSTRIAL FISHERY

3.1. Vessels Active and Trip Information

- Readers should note that catches reported during year 2025 and 2024 relates to 100% logbook returned to SFA.

- Over the past decade, the semi-industrial longline fishery has expanded significantly. The number of active vessels increased from 11 vessels in 2015 to 65 vessels in 2024. Similarly, the total number of fishing trips increased from 56 in 2015 to 536 in 2024. Additionally, the average duration of each trip extended from 13 days (2015-2019) to an average of 21 days per trip in 2024 (table 3.0).

- In 2025, 64 vessels conducted a total of 489 fishing trips, primarily targeting tuna. This marks a 9% decrease in the number of trips compared to the 536 trips conducted by 65 vessels in 2024. The average trip duration increased from 21 days per trip in 2024 to 24 days per trip in 2025 (Table 3.0). On average, each vessel undertook 8 trips per year in 2025, similar to the previous year.

- In summary, over the past decade, the semi-industrial longline fishery has experienced significant growth, with notable increases in both number of vessel and fishing activity. The fleet expanded steadily, and fishing trips became more frequent and longer in duration. In 2025, the number of active vessels decreased, resulting in a corresponding decline in the total number of fishing trips compared with the previous year. Despite this reduction in fleet activity, the average trip duration continued to increase.

3.2. Fishing Effort, Catches and Catch Rate

- Over the past decade, semi-industrial longline catches have shown a dynamic pattern. From 2015, catches increase steadily from 195 MT to reach 2,008 MT by 2019. In 2020, the catch decreased by 26% to 1,485 MT due to the Covid-19 pandemic, which led some vessels to switch to targeting demersal species. Thereafter, a significant increase in catch levels was observed, reaching 2,536 MT in 2023, the highest annual catch recorded since the beginning of the fishery. This was followed by a 17% decline in 2024, resulting in a total catch of 2,102 MT (Figure 3A).

- A similar trend has been observed in fishing effort within the semi-industrial fishery. Since 2015, the fishing effort showed a consistent increase, from 205,505 hooks to about 2.5 million hooks by 2019. In 2020, a 20% reduction occurred due to the Covid-19 pandemic. However, fishing effort has been on an upward trend since then to reach a total of 6.8 million hooks in 2024 (figure 3B).

- The CPUE fluctuated between 0.54 MT/1000 hooks and 0.95 MT/1000 hooks during the 2014 to 2019 period and has since then been on a downward trend (figure 3C).

- During the year 2025, the Semi industrial fishery reported a total catch of 1,965 MT. This represents a 6% decline from the 2,102 MT recorded in 2024 corresponding to a 9% decrease in fishing effort, with approximately 6.2 million hooks set in 2024 compared to 6.8 million hooks in 2024 (Table 3.0). Consequently, the mean catch rate estimated for the year 2025 stands at 0.32 MT/ 1000 hooks compared to a mean catch rate of 0.31 MT/ 1000 hooks estimated for the previous year. This is the second lowest catch rate reported since the beginning of the fishery.

- In summary, over the past decade, semi-industrial longline catches and fishing effort have shown remarkable expansion, with catches reaching record levels in 2023. However, both catch and fishing effort decreased in 2025, resulting in the catch rate declining to its second-lowest level since the beginning of the fishery.

3.3. Species Composition

- Historically, swordfish was the primary target species for the semi-industrial longline fishery (figure 3D). However, since 2015, yellowfin tuna has overtaken swordfish as the dominant species caught. The yellowfin tuna catch has increased significantly from 98 metric tons (MT) in 2015 to 2,376 MT in 2023. In 2024, catches declined by 22% to 1,853 MT. Swordfish catches also increased from 47 MT in 2015 to 313 MT in 2019 and has subsequently been on a downward trend. Bigeye tuna catches increased from 33 MT to 119 MT during the same period. However, both swordfish and bigeye tuna catches declined to 60 MT and 34 MT, respectively, in 2023. In 2024, bigeye tuna catches increased remarkably by 281%, reaching 131 MT, while swordfish catches declined by 16%.

- In 2025, yellowfin tuna comprised 79% of the total catch in the semi-industrial fishery, while bigeye tuna contributed 11%. Swordfish, marlin and sailfish represented 4%,3% and 2% of the total catch respectively (figure 3E). During the previous year, the catch composition consisted of 88% yellowfin tuna, 6% bigeye tuna, with swordfish and marlins each accounted for 2% of the total catch.(figure 3f).

- In 2025, the semi-industrial longline fishery recorded notable changes in the composition of its catch compared with 2024. Catches of bigeye tuna, swordfish, sailfish, and marlin increased, while catches of yellowfin tuna and sharks declined. Bigeye tuna reached a record high of 223 MT, the highest catch recorded since the beginning of the fishery, representing a substantial increase of 71% over the 131 MT reported in 2024. Sailfish catches also increased significantly by 127% from 14 MT in 2024 to 33 MT in 2025. Similarly, swordfish and marlin catches increased by 62% and 44%, respectively, over the same period. In contrast, shark catches declined sharply by 53%, while yellowfin tuna catches decreased by 16% compared with 2024.

- In summary, historically, swordfish dominated catches in the semi-industrial longline fishery, but since 2015, yellowfin tuna has become the primary species, showing a sharp increase over time. In 2025, yellowfin tuna remained the main species, though its proportion of total catches and volume landed decreased compared to the

previous year. Conversely, bigeye tuna recorded its highest catch ever, while catches of swordfish, sailfish, and marlin also increased, indicating a shift in species composition and targeting trends within the fishery.

Artisanal Fishery

4. SUMMARY OF ARTISANAL FISHERY

In 2024, the Seychelles Fisheries Authority (SFA) upgraded its data processing system for the artisanal fishery. As a result, SFA is currently reprocessing historical artisanal fishery data to produce more refined and disaggregated statistics. This reprocessing is a time-consuming task and will be carried out in phases. Consequently, this report includes only the data for the years 2018 to 2025 whereby data from the year 2022 to 2025 have been processed using the new system.
Readers should be aware that the estimates presented in this report may differ from previously published figures. For more details on the revised processing methods, please refer to the description of the fishery data management at the beginning of this report on page *XVII*.

4.1. Vessel Active

- From 2019 to 2023, the average number of boats operating each month in the artisanal fishery declined steadily. This downward trend coincided with the period during and immediately following the COVID-19 pandemic, which affected fisheries operations, market access, and economic conditions. Over the same period, notable changes occurred in fleet composition, with a gradual shift from smaller vessels to larger and more seaworthy craft. The average number of outboard vessels, traditionally the most common vessel type in the artisanal fishery, decreased consistently, while schooners recorded a steady increase in monthly activity. In contrast, the number of whalers remained relatively stable, averaging approximately 53 vessels per month throughout the period (Table 4.1A).

- Following four consecutive years of declining activity, the artisanal fishery experienced a notable recovery in 2024. The average number of active boats increased by 13%, increasing from 282 vessels per month in 2023 to 318 vessels per month in 2024 (Table 4.1B). This recovery was evident across all major boat categories. Outboard vessels increased by 13%, rising from an average of 169 to 190 boats per month. Schooners and whalers also recorded increases of 17% and 7%, respectively, with the average number of active schooners increasing from 55 to 64 boats per month and whalers from 50 to 54 boats per month.

- In 2025, the composition of the artisanal fleet remained broadly consistent with that observed in 2024, indicating that the recovery achieved in the previous year was largely sustained. Outboard vessels continued to dominate the fleet and accounted for the largest share of active vessels. However, the average monthly activity of outboard vessels declined by 8% compared with 2024. Similar reductions were observed among schooners and whalers. In contrast, the vessel group classified as “Others” recorded substantial growth, increasing by 48% from an average of 7 active boats per month in 2024 to 11 boats per month in 2025. Although this category represents a relatively small proportion of the total fleet, its rapid growth suggests

increasing participation by less common vessel types and may indicate diversification within the artisanal fishing sector.

4.2. Catch Statistic by Vessel Type

- Analysis of the artisanal fishery catch time series revealed a significant decline in production during 2020, when total catches fell by 20% compared with the previous year. This decline coincided with the disruptions associated with the COVID-19 pandemic and represented the largest annual reduction recorded during the study period. Following this decline, total catches stabilized between 2021 and 2023, averaging 4,187.9 MT annually (Table 4.2 and Figure 4A). Although the fishery demonstrated resilience during these years, catch volumes remained relatively unchanged, indicating a period of recovery without substantial growth in production.

- A marked improvement was observed in 2024, when total artisanal catches increased by 11% to reach 4,623.3 MT. This increase corresponded with the increase in mean number of boat active per month observed during the same year. The increase in catches was observed across all boat categories except schooners, which recorded a decrease of 17% in catches.

- In 2025, however, total estimated catches declined by 12% to 4,077.1 MT despite the relatively stable fleet composition. The decline was driven primarily by whalers, whose estimated catches fell by 41%, from 1,251.0 MT in 2024 to 737.6 MT in 2025. In contrast, catches from outboard vessels and schooners remained relatively stable at 1,631.0 MT and 1,626.2 MT, respectively. Catches from pirogues and vessels classified as “Others” increased by 7% and 106%, respectively. The substantial increase recorded by the “Others” category, from 54.9 MT in 2024 to 113.0 MT in 2025, is likely associated with the corresponding 55% increase in the average number of these boats operating each month.

- Historically, outboard vessels have been the dominant contributors to artisanal fishery production. However, this pattern began to change in 2023, when schooners emerged as the leading vessel category, accounting for 47% of total catches. The trend continued in 2024, with schooners contributing 35% of total catches, slightly exceeding the contributions of outboard vessels (34%) and whalers (27%), (Table 4.2A).

- In 2025, schooners maintained their position as the leading boat category category, accounting for 40% of total artisanal catches, closely followed by outboard vessels with 39%. Whalers accounted for 18% of total catches, representing a substantial decline from their 27% contribution in 2024. Meanwhile, the contribution of the “Others” category increased from 1% to 3% of total catches, further reinforcing evidence of the growing role of these less common vessel types within the fishery.

- Overall, the catch composition statistics suggest that the artisanal fishery continues to undergo gradual structural changes, with schooners consolidating their importance

while emerging boat categories make increasingly noticeable contributions to total production of the artisanal fishery.

4.3. Catch Statistics by Gear Type

- Analysis of artisanal fishery catches by gear type shows that handline fishing has consistently been the dominant fishing method, accounting for an average of approximately 72% of total annual catches between 2020 and 2024 (Table 4.3 and Figure 4C). Encircling gillnets ranked as the second most important gear type, contributing an average of 14% of total catches over the same period. In comparison, active and static traps combined accounted for approximately 10% of total landings, while catches from harpoons, droplines, hoop/tangle nets, and other fishing gears remained relatively small. The predominance of handline fisheries reflects the heavy reliance of the artisanal sector on hook-and-line fishing methods.

- In 2025, the overall catch composition by gear type remained largely consistent with historical patterns, with handlines contributing 2,989.0 MT, equivalent to 73% of the total artisanal catch. Encircling gillnets remained the second most important gear category and recorded a notable increase in their contribution to total catches, increasing from 11% in 2024 to 18% in 2025. Meanwhile, active and static traps together contributed approximately 8% of total catches, slightly below their long-term average contribution.

- Changes in catch volumes between 2024 and 2025 varied considerably across gear types. Total artisanal production decreased by 11%, from 4,623.3 MT in 2024 to 4,077.1 MT in 2025, and this decline was primarily driven by reductions in catches from handlines, traps, and droplines.

- Handline catches decreased by 10%, from 3,308.1 MT to 2,989.0 MT. Similarly, catches from trap fisheries declined substantially, combined catches from active and static trap fisheries declining from 493.1 MT in 2024 to 328.1 MT in 2025, representing a reduction of approximately 33%. The most substantial proportional decline was recorded for dropline fisheries, where catches fell by 89%, from 160.0 MT in 2024 to only 17.2 MT in 2025. This sharp decrease was largely attributable to extremely low fishing effort, with only a single dropline fishing trip reported during 2025. Other minor gear categories also recorded declines, including harpoons, whose catches decreased from 51.5 MT to 18.1 MT, and hoop/tangle nets, which declined from 46.5 MT to 10.8 MT.

- In contrast, encircling gillnets were the only major gear category to record an increase in catches during 2025, rising by 29%, from 553.0 MT in 2024 to 713.7 MT in 2025.

- Overall, the 2025 catch composition highlights the continued dominance of handline fisheries within the artisanal sector, while also revealing the important role for encircling gillnets. The increase in gillnet catches contrasted with widespread declines among most other gear types and resulted in a noticeable shift in catch composition. Nevertheless, handlines and encircling gillnets together accounted for over 90% of

total artisanal catches in 2025, underscoring their importance to the productivity and performance of the artisanal fishery.

4.4. Catch Statistics by Species

- Historically, artisanal fishery production between 2018 and 2024 was dominated by trevally (karang), jobfish (zob), Indian mackerel (makro dou), and emperor red snapper (bourzwa), which contributed an average of approximately 30%, 14%, 10%, and 9% of total annual landings, respectively (Table 4.4). Trevally remained the principal species landed throughout the period, although catches fluctuated considerably, ranging from a high of 1,742.2 MT in 2018 to 1,071.0 MT in 2021. Jobfish catches remained relatively stable between 2018 and 2022, averaging around 601 MT annually, before increasing substantially to 847.3 MT in 2023 and 906.1 MT in 2024. Indian mackerel exhibited marked interannual variability, peaking at 637.8 MT in 2019 before declining to 311.3 MT in 2023. Emperor red snapper catches also fluctuated over time, reaching a peak of 562.0 MT in 2019 before stabilizing between 319 and 434 MT during 2020-2024.

- In 2025, total artisanal landings declined by 12%, from 4,623.3 MT to 4,077.1 MT. This reduction was largely observed among several key species. Trevally (Karang) landings fell by 17%, from 1,149.7 MT in 2024 to 956.3 MT in 2025, while jobfish (zob) declined by 20%, from 906.1 MT to 724.4 MT. Emperors (kaptenne) experienced one of the sharpest reductions, decreasing by 45% from 368.2 MT to 201.0 MT. Other notable declines were observed for sharks and rays (-90%), crabs (-77%), octopus (-64%), other trap fish (-39%), and other groupers (-40%).

- In contrast, several species recorded significant increases in 2025. Indian mackerel (makro dou) landings increased by 65%, rising from 317.0 MT in 2024 to 523.6 MT in 2025, representing the largest increase among the major commercial species. Other snappers also increased substantially by 41%, from 299.0 MT to 420.2 MT, while other mackerel more than doubled, increasing from 25.2 MT to 54.3 MT. Emperor red snapper (bourzwa) catches remained relatively stable, increasing marginally by less than 1%, from 434.0 MT to 436.6 MT.

- Despite the reduction in overall landings, trevally remained the dominant species in the artisanal fishery during 2025, contributing 23% of total catches. Jobfish remained the second most important species, accounting for 18% of total catches. A notable shift in species composition was observed with Indian mackerel, whose contribution increased from 7% of total landings in 2024 to 13% in 2025, making it the third largest contributor to artisanal production. Emperor red snapper accounted for 11% of total catches in 2025, compared with 9% in 2024.Other changes in species composition included an increase in the share of other snappers from 6% to 10% of total landings.

- Overall, the 2025 species composition indicates a shift in landing patterns away from traditionally dominant species such as trevally and jobfish towards increased contributions from Indian mackerel and other snapper species.

4.5. Fishing Effort by Vessel Type and Gear Type

- **Handline Fishery**: Fishing effort in the handline fishery has generally increased over the 2018-2024 period, rising from 65,797 men-days in 2018 to 106,567 men-days in 2024 (Table 4.5 and Figure 4M). While effort fluctuated during this period, including a notable decline to 69,375 men-days in 2022, the fishery experienced strong increase in 2023 and reached its highest recorded level in 2024. This increase was largely driven by increased fishing effort among schooners and whalers, with schooners accounting for 46,610 men-days and whalers contributing 39,112 men-days in 2024. Outboard vessels, traditionally important in the fishery, recorded a gradual decline in effort over the same period.

- In 2025, fishing effort declined substantially across most vessel categories, with total estimated effort decreasing to 68,606 men-days, representing a 36% decline compared with 2024. The reduction was primarily driven by lower activity among schooners, whose effort decreased by 29% from 46,610 men-days to 33,081 men-days, and whalers, which fell by 52% from 39,112 men-days to 18,867 men-days. Effort by outboard vessels remained relatively stable, declining marginally from 14,994 men-days to 14,892 men-days. Despite the reduction in overall effort, schooners remained the dominant vessel category, accounting for nearly half of all handline fishing effort during 2025. The sharp decline in effort reflect reduced fishing activity within the handline sector and may partly explain the lower catch levels observed during the year.

- **Trap Fishery**: Fishing effort in the trap fishery has followed a long-term declining trend since 2018, with the total number of traps deployed falling from 120,193 traps in 2018 to 48,992 traps in 2023 (Figure 4N). This reduction reflected declining activity among outboard vessels, which consistently account for the majority of trap fishing operations. In 2024, however, effort rebounded strongly to 66,080 traps, representing a 40% increase compared with 2023. The recovery was driven by increased traps set across all major boat categories, particularly outboard vessels, which accounted for approximately 90% of all traps set.

- In 2025, trap fishing effort remained relatively stable, with an estimated 62,086 traps set during the year. Although this represents a 9% decrease compared with 2024, effort remained substantially higher than levels recorded in 2023. Outboard vessels continued to dominate the fishery, contributing 59,524 traps, or approximately 93% of total traps set. Declines were observed among whalers and schooners, although activity by "other" vessel categories increased considerably from 1,276 traps in 2024 to 2,517 traps in 2025. Overall, the trap fishery demonstrated greater stability than the handline fishery in 2025 and remained an important component of artisanal fishing activity.

- **Net Fishery:** Fishing effort in the net fishery has fluctuated considerably over the review period. Following an increase from 2,148 net sets in 2018 to 3,204 sets in 2019, effort declined sharply in 2020 and remained relatively low through 2024 (Figure 4O) although there was a spike in 2022 to 3,311 sets. Net fishing activity reached 2,606

sets in 2024, representing modest growth compared with previous years but remaining below levels observed at the beginning of the time series.

- In 2025, net fishing effort increased substantially to an estimated 3,545 net sets, representing a 36% increase compared with 2024 and the highest level recorded during the 2018-2025 period. This increase was driven almost entirely by outboard vessel operations, which accounted for 3,496 sets, representing approximately 99% of total net fishing effort. In contrast, effort by pirogues continued to decline, falling from 68 sets in 2024 to only 49 sets in 2025. The sharp increase in outboard-based net fishing activity indicates a greater reliance on this fishing method during the year and is consistent with the substantial increase in Indian mackerel landings recorded in 2025. The increase in net fishing effort likely reflects improved availability of small pelagic species and fishers' response to the associated fishing opportunities.

- Analysis of fishing effort by gear and vessel type indicates contrasting trends across the artisanal fisheries in 2025. The handline fishery, which had experienced sustained growth and reached a peak in 2024, recorded a substantial decline in effort during 2025, largely due to reduced activity among schooners and whalers. In contrast, the trap fishery remained relatively stable, maintaining effort levels close to those observed in 2024 and continuing to rely heavily on outboard vessels. The net fishery showed the strongest growth, with effort increasing markedly due to expanded outboard operations.

- Overall, total fishing effort patterns in 2025 suggest a shift away from the highly effort-intensive handline sector towards greater reliance on trap and net fishing activities. While outboard vessels remained dominant within the trap fishery and the net fishery, schooners continued to play a central role in handline operations despite their reduced activity.

4.6. Catch Rate by Vessel Type and Gear Type

- **Handline Fishery (Artisanal Boats**): Catch rates for artisanal vessels using handline gear have generally declined over the review period, decreasing from 56.1 kg per men-day in 2018 to 32.5 kg per men-day in 2024, the lowest level recorded during the time series (Table 4.6 and Figure 4S). Catch rate by boat type varied slightly in 2024, with outboard vessels averaging 33.9 kg per men-day, whalers 31.6 kg per men-day, and schooners 34.2 kg per men-day. The highest catch rate was recorded by the category classified as "Other" vessels, which achieved 40.5 kg per men-day.

- In 2025, handline catch rates improved across most vessel categories, resulting in an overall average catch rate of 43.8 kg per men-day. Schooners recorded the highest catch rate among the main boat categories at 48.9 kg per men-day, followed by whalers (38.9 kg per men-day) and outboard vessels (37.6 kg per men-day). The "Other" vessel category achieved the highest overall catch rate at 58.8 kg per men-day.

- **Trap Fishery**: Catch rates in the trap fishery have generally increased over the review period, from 3.9 kg per trap in 2018 to 7.5 kg per trap in 2024, The highest catch rate recorded in the series despite a temporary decline in 2020 (Figure 4T). Higher catch rates were observed across several vessel categories, particularly schooners (12.0 kg per trap) using hoop and tangle net targeting crabs and other vessels (12.9 kg per trap) using mainly traditional static and active traps.

- In 2025, trap fishery productivity declined markedly. The overall catch rate fell to 5.3 kg per trap, representing a 31% decrease compared with 2024. Outboard vessels, which accounted for the majority of trap-fishing effort, recorded a catch rate of 5.2 kg per trap, compared with 7.5 kg per trap in the previous year. Similar declines were recorded among whalers, schooners and other vessels, with schooners experiencing the largest reduction from 12.0 kg per trap to 5.7 kg per trap. The widespread decline in CPUE suggests reduced trap fishery productivity during 2025, possibly reflecting lower abundance or availability of species targeted by traps.

- **Net Fishery**: The catch rate in the net fishery has fluctuated considerably since 2018 but has generally shown a declining trend. Overall CPUE decreased from 420.7 kg per set in 2018 to 181.8 kg per set in 2023, although temporary increases were observed during some years. In 2024, CPUE recovered slightly to 212.2 kg per set.

- In 2025, the average catch rate declined marginally to 201.3 kg per set, representing a 5% decrease compared with 2024. Catch rates varied between the two boat type, with pirogues recording 164.1 kg per set and outboard vessels 201.8 kg per set. Despite the lower CPUE, the net fishery experienced a substantial increase in fishing effort, resulting in higher overall catches.

4.7. Activities by Landing Site

Readers should note that some boats may operate from multiple landing sites during the year. As a result, the mean monthly number of vessels operating (Table 4.1) may differ from the annual number of vessels recorded (Table 7.0A).

- **Mahé**: Mahé remained the dominant fishing island in 2025, with an average of 302 artisanal fishing boats operating throughout the year and an estimated 3,597.0 MT of catches landed, representing 88% of total artisanal production. In 2024, an average of 307 boats landed 4,148.5 MT, accounting for 90% of national artisanal catches. While the number of operating vessels remained relatively stable, total landings declined by approximately 13% in 2025, indicating lower catch rates compared with the previous year. Fishing effort and production continued to be concentrated at a small number of key landing sites.

- The distribution of fishing activity on Mahé remained highly concentrated among a small number of landing sites. Based on mean vessel numbers, Providence (56 boats), Victoria (55 boats), and La Retraite (40 boats) were the main landing sites in 2025, collectively accounting for approximately half of all operating vessels on the island.

Cascade (26 boats) and Belombre (17 boats) also supported relatively significant number of boats.

- A similar concentration was observed in terms of production. Victoria remained the leading artisanal landing port, with a total estimated landing of 1,025.2 MT or 25% of total artisanal landings in 2025. Providence ranked second with 803.2 MT accounting for 20% of total catches, while 611.2 MT was landed at La Retraite accounting for 15%. Combined, these three landing sites accounted for approximately 60% of total estimated artisanal landings.

- Although Victoria remained the largest landing site, production declined from 1,167.7 MT in 2024 to 1,025.2 MT in 2025, representing a reduction of approximately 12%. A more significant decline was observed at Providence, where landings decreased by 19% from 997.1 MT to 803.2 MT. In contrast, landings at La Retraite increased from 565.2 MT to 611.2 MT, an increase of approximately 8%, increasing its share of total artisanal production from 12% to 15%.

- Among the remaining major landing sites, Belombre recorded the most substantial decline, with landings decreasing from 570.7 MT in 2024 to 317.3 MT in 2025, a reduction of approximately 44%. Smaller decreases were also observed at Cascade (-12%).

- **Praslin:** On Praslin it was estimated that on average 44 boats operated in 2025 and landed a total estimated catch of 363.0 MT, representing approximately 9% of total artisanal catches, compared with 371.7 MT landed in 2024 representing 8% of total artisanal catches for that year. Boat activity and production remained concentrated at Baie Ste Anne, where an average of 17 boats operated and landed an estimated total of 247.9 MT, equivalent to approximately 68% of the island's total landings. Flying Deutchman/Grand Anse was the second most important landing site, with a mean of 12 boats operating and landing an estimated 83.8 MT. In comparison, landings at Baie Ste Anne and Flying Deutchman/Grand Anse were 228.2 MT and 80.0 MT, respectively, in 2024.

- Overall, Praslin experienced only minor changes in 2025, with a slight reduction in mean number of boats operating but relatively stable catch volumes.

- **La Digue**: On average, 16 boats operated on La Digue in 2025 with a corresponding landing of 117.1 MT, representing approximately 3% of total artisanal catches, compared with 103.1 MT in 2024. Fishing activity and production remained almost entirely concentrated at La Passe, where on average 15 of the 16 boats operate and an estimated total catch of 116.9 MT was landed in 2025, compared with 102.8 MT the previous year.

- Despite a reduction in number of boat operating compared with the previous year, total landings increased by approximately 14%.

4.8. Summary

- In summary, the artisanal fishery experienced a decline in production during 2025, with total landings decreasing by 12% from 4,623.3 MT in 2024 to 4,077.1 MT, despite relatively stable levels of vessel activity.

- Outboard vessels remained the most prevalent vessel type, while schooners continued to be the principal contributors to total landings.

- Handline fisheries remained the dominant fishing method, accounting for 73% of total artisanal production, although catches from both handline and trap fisheries declined compared with the previous year.

- The reduction in total landings was primarily associated with lower catches of key commercial species, particularly trevally and jobfish, as well as reduced landings at major landing sites on Mahé, notably Victoria, Providence, and Belombre. Conversely, increases in gillnet catches and landings of Indian mackerel partially offset these declines.

- Fishing activity and production remained highly concentrated on Mahé, which accounted for 88% of total artisanal landings, while production on Praslin and La Digue remained comparatively stable.

** Note: Differences between the mean number of vessels operating per month (Table 4.1) and the annual number of vessels recorded arise because some vessels operated from multiple landing sites during the year.*

Consequently, a vessel may be recorded at more than one landing site over the course of the year, resulting in annual totals that are not directly comparable with monthly averages.

5. Sea Cucumber Fishery

5.1 Catch

For the 2024/2025 fishing season, landings totalled 181,588 sea cucumbers pieces while the 2025/2026 season it totalled 183,899 pieces. Flower Teatfish constituted the largest proportion with 146,789 pieces in 2024/2025 and 151,399 pieces in 2025/2026. This was followed by Prickly Redfish at 27,231 pieces in 2024/2025 and 23,682 pieces for the 2025/2026 fishing season. For the 2024/2025, a total of 3,286 pieces of Golden Sandfish were landed and 6,888 pieces were landed for the 2025/2026 season. A total of 3,286 pieces of White Teatfish pieces were landed in 2025/2026 and 1,611 pieces in 2025/2026, while Black Teatfish accounted for only 657 pieces in 2024/2025 and 319 pieces in 2025/2026 (Table 5.1).

For the 2024/2025 season, the percentage of the assigned quota reached was 68.2% for Flower Teatfish, 59% for Prickly Redfish, and 3.7% for Golden Sandfish. While for the 2025/2026 season, the quota utilisation was 75.7% for Flower teatfish, 62.2% for Prickly Redfish and 8.9% for Golden sandfish.

5.2 Effort

Over the years, fishing efforts have fluctuated, with periods of increase and decline. In the 2024/2025 season, 112 trips were completed, representing a decrease of 25 trips compared to the 2023/2024 season (137 trips), which was 10 trips more than the 2022/2023 season. In the 2025/2026 fishing season the number of trips were only 92 trips, which was a noticeable decline compared to previous years. (see Table 5.2)

Table 5.1: Sea Cucumber landings by species and fishing seasons.

Species	2015/2016	2016/2017	2017/2018	2018/2019	2019/2020	2020/2021	2021/2022	2022/2023	2023/2024	2024/2025	2025/2026

Lobster Fishery

6. SUMMARY OF LOBSTER FISHERY

6.1. Catch

The overall lobster catch for the 2023 fishing season was 3.32 MT compared to 2.05 MT in 2021/2022 and 6.14 MT in the 2020/2021 season, representing a 62% increase and 46% decrease, respectively. The lobster fishery catch fluctuates from season to season. The highest catch of 6.14 MT was recorded in the 2020/2021 season, whereas the lowest catch of 0.61 MT was recorded in the 2013/2014 season (Table 6.1). Some seasons of the lobster fishery remained closed due to declines in stock indicators that are monitored during the fishery and fishery-independent surveys. A notable peak in catch was recorded in 2019/2020 following a two-year closure. The 2023 catch was 21% lower than the historical mean of 4.20 MT.

In terms of catch composition for the targeted species, historically, *P. penicillatus* dominated the catch for all seasons with an average of 2.8 MT per season, followed by *P. longipes* with an average of 1.0 MT per season. In the 2023 fishing season, a total of 2.21 MT of *P. penicillatus* was recorded, representing 66.8% of the total catch. For the same period, *P. longipes* contributed to 1.0 MT or 29.6% of the total catch. *P. versicolor* and *P. ornatus* were less abundant, with catches of 0.07 MT (2.2%) and 0.05 MT (1.4%), respectively (Table 6.1, Figure 6A). Snorkelling was the predominant fishing method, accounting for 95% of the total catch (Table 6.2, Figure 6B).

6.2. Effort

A total of 135 fishing trips were recorded during the 2023 fishing season compared to 103 trips in 2021/2022 and 242 trips in 2020/2021, representing an increase of 31% and a decrease of 44%, respectively (Table 6.3).

6.3. Catch per unit effort

The overall CPUE for the 2023 fishing season was 24.6 kg/trip compared to 19.9 kg/trip for 2021/2022 and 25 kg/trip for 2020/2021. The 2023 CPUE was 27% higher than the historical mean of 19.3 MT, reflecting a 24% increase compared to the 2021/2022 season and a 3% decrease compared to the 2020/2021. CPUE varied over the years; the highest CPUE recorded was 27.65 kg/trip in the 2019/2020 season, while the lowest was 10.14 kg/trip in 2012/2013 (Table 6.3).

6.4 Catch and Effort Data Unavailable

The lobster fishery was closed for two consecutive seasons, 2023/2024 and 2024/2025. Catch and effort data are therefore unavailable for both seasons.

Table 6.1: Lobster catch in metric tonnes by species and seasons.

Export & Import of Fish And Fish Products

7. SUMMARY OF EXPORT OF FISHERIES PRODUCT

***Disclaimer**: All data presented in this section are secondary data obtained from the National Bureau of Statistics (NBS). Variations may occur between the figures published here and those previously released by NBS, particularly if preliminary estimates were available at the time of publication.*

7.1. Export of Fish and Fish Product (Volume & Value)

- In 2025, exports of fish and fish products recorded a strong expansion, with export volume increasing by 76% to 110,695 MT and export earnings rising by 24% to SCR 5.4 billion compared with 2024. This performance was largely underpinned by the substantial increase in exports of fresh and frozen fish. During the first half of the year, export volume increased by 34% to 40,067 MT, while export value declined marginally by 1% to SCR 2.1 billion, indicating lower average export prices. In contrast, the second half of the year registered significantly stronger growth, with export volume increasing by 115% to 70,627 MT and export value rising by 48% to SCR 3.3 billion, reflecting both higher shipment volumes and improved market demand.

- The overall growth in fish exports was driven primarily by the **fresh and frozen fish** segment, which recorded an exceptional increase of 419% in volume and 442% in value, reaching 60,703 MT valued at SCR 1.5 billion. The average export price strengthened slightly from SCR 23.40 per kilogram in 2024 to SCR 24.43 per kilogram in 2025, suggesting stable market conditions despite the substantial increase in supply. Tuna species continued to dominate this category, accounting for approximately 90% of total fresh and frozen fish exports, followed by other fish species (7%) and small pelagic species (2%).

- Exports of **sea cucumber** also recorded a strong recovery, increasing by 109% in volume and 33% in value to 95 MT worth SCR 78.2 million. However, average export prices declined significantly from SCR 1,293.62 per kilogram to SCR 823.99 per kilogram, indicating weaker international prices.

- In contrast, **canned tuna** exports experienced a moderate contraction in 2025. Export volume declined by 6% to 40,918 MT, while export earnings decreased by 5% to SCR 3.6 billion. Despite this decline, the average export price increased marginally from SCR 88.13 per kilogram to SCR 88.52 per kilogram, suggesting that the reduction in export value was largely volume-driven rather than price-related. Nevertheless, canned tuna remained the largest export category in terms of earnings accounting for, accounting for a substantial 67% share of total fish export revenue.

- Exports of **fish meal** continued to expand, with export volume increasing by 17% and export value rising by 13% to reach 8,213 MT valued at SCR 159.6 million. The lower growth in value relative to volume reflects a decline in the average export price to SCR 19.43 per kilogram, indicating softer market prices during the year.

- Exports of **fish oil and fat** remained relatively stable in volume at approximately 690 MT, generating SCR 35.1 million in export earnings. However, average export prices declined to SCR 50.88 per kilogram, suggesting weaker price conditions in destination markets. Overall, while

fish oil and fat continued to contribute modestly to export earnings, their performance remained relatively low compared with other fish product categories.

7.2. Export of Fish and Fish Product by Destination

- Export destinations for fish and fish products exhibited notable shifts in 2025, reflecting evolving market preferences and changing trade patterns across key product categories.

- Hong Kong remained the principal market for dried **sea cucumber**, accounting for 78% of total exports, while the Republic of China emerged as the second-largest destination with a 22% share. This represents a notable change from 2024, when Malaysia accounted for 4% of exports. Sea cucumber remained the most geographically concentrated export product, being shipped to only two destination markets in both years.

- Exports of **fresh and frozen fish** became considerably more diversified in 2025. Côte d'Ivoire, Spain, and Thailand were the leading destinations, accounting for 24%, 18%, and 16% of total exports, respectively. This marks a significant shift from 2024, when Côte d'Ivoire alone absorbed 62% of total exports within this category.

- **Canned tuna** exports continued to be heavily concentrated within the European market. France remained the leading destination, receiving 35% of total canned tuna exports, followed by Germany (23%), the United Kingdom (16%), and Italy (12%). Compared with 2024, the share exported to Germany increased, while the United Kingdom's share declined. These changes may reflect shifting consumer demand, competitive market conditions, and evolving trade relationships within Europe.

- Exports of **fish meal** displayed greater market diversification during 2025. Bangladesh emerged as the largest destination, accounting for 26% of exports, followed by Turkey (22%), Taiwan (14%), and Australia (13%). This contrasts with 2024, when Turkey was the dominant importer with 25%, followed by Germany (17%), Taiwan (15%), Australia (15%), and Bangladesh (14%).

- For fish oil and fat, Spain became the leading export destination in 2025, accounting for 58% of total exports, while Germany received 28%. This represents a significant reorientation of trade flows compared with 2024, when Iceland dominated the market with a 74% share and Germany accounted for 17%. The shift suggests the emergence of new market opportunities within Southern Europe.

- The observed changes in export destinations underscore the fisheries sector's increasing integration into a wider range of international markets. Greater market diversification, particularly for fresh and frozen fish and fish meal, may enhance export resilience by reducing dependence on a limited number of trading partners. At the same time, the continued concentration of canned tuna exports within Europe and sea cucumber exports within East Asian markets highlights the importance of maintaining strong trade relationships in these established markets.

8. SUMMARY OF IMPORT OF FISHERIES PRODUCT

Disclaimer: *All data presented in this section are secondary data obtained from the National Bureau of Statistics (NBS). It should be noted that species composition for fresh and frozen fish exports is largely aggregated, due to the raw data not reported at species level. Figures published here may differ from those previously released by NBS, particularly if only preliminary estimates were available at the time of publication.*

8.1. Import of Fish and Fish Product (Volume & Value)

- In 2025, the overall import of fish and fish products showed mixed trends. Total import volume declined by 28% to 50,158 MT, while import value increased by 10% to SCR 2.1 billion compared to 2024. During the first semester, import volume remained broadly unchanged at 35,887 MT, valued at SCR 0.96 billion. However, imports weakened significantly during the second semester, with volume declining by 58% to 14,270 MT, while value increased by 20% to SCR 1.1 billion (Table 8.1). The divergence between volume and value indicates a substantial increase in the average import price of fish and fish products.

- **Fresh and frozen fish** imports accounted for the largest share of total fish imports, amounting to 49,302 MT valued at SCR 1.95 billion. Compared to 2024, import volume decreased by 28%, while value increased by 10%. The average import price increased significantly from SCR 25.71/kg in 2024 to SCR 39.52/kg in 2025. As the dominant product category, fresh and frozen fish largely drove the overall import trend. The substantial increase in unit value despite lower import volumes suggests a notable rise in international fish prices. Given that imports continued to be sourced primarily from European suppliers as in 2024, the increase in import expenditure is likely attributable to higher purchase prices rather than a shift in product origin.

- **Crustacean** imports increased by 23% in volume and 28% in value, reaching 439 MT and SCR 64.9 million, respectively. The average import price remained relatively stable at SCR 148.76/kg in 2025 compared to SCR 142.64/kg in 2024. The growth in both volume and value suggests stronger domestic demand for crustacean products. The relatively stable unit price indicates that increased expenditure was primarily driven by higher import volumes rather than significant price inflation.

- Similarly, **Mollusc** imports increased by 31% in volume and 15% in value, amounting to 328 MT valued at SCR 25.7 million. The average import price remained relatively stable at around SCR 179.59/kg. The stronger growth in import volume relative to value resulted in a slight moderation of the average price.

- Imports of **dried, smoked, salted and brined fish** declined by 5% in volume but increased by 21% in value, reaching 20 MT and SCR 5.4 million, respectively. The average import price increased to SCR 273.2/kg. The decline in volume alongside higher import cost suggests that rising prices were the main driver of increased import value.

- Canned fish imports declined by 20% in volume to 68 MT, while value increased by 8% to SCR 7.2 million. The higher import cost is attributed to a sharp increase in average prices from SCR 78.63/kg to SCR 105.9/kg.

8.2. Import of Fish and Fish Product by country of Origin

- In 2025, the sourcing pattern of fish and fish product imports changed notably compared to 2024. Spain overtook France as the leading supplier of **fresh and frozen fish**, accounting for 60% of total imports, while France contributed 31%. This compares with 2024 when France represented 48% of imports and Spain 45%.

- **Crustacean** imports continued to be sourced mainly from India, which supplied 61% of the total, followed by the United Arab Emirates (UAE) with 32%, a slight change from 2024 when India and UAE accounted for 55% and 32%, respectively.

- Similar to Fresh and Frozen fish, Spain emerged as the principal supplier in 2025 for **molluscs, including oysters**, accounting for 59% of imports, while France supplied 31%. In 2024, Spain and France accounted for 45% and 48%, respectively. The continued dominance of European suppliers indicates the importance of established trade links for seafood products.

- Imports of were sourced mainly from the UAE and France in 2025, accounting for 56% and 39% of imports, respectively. In comparison, France accounted for 45% and the UAE 38% in 2024.

Vessel Expenditures

9. SUMMARY OF VESSEL EXPENDITURES

9.1. Bunkering

- Data from the Seychelles Petroleum Company (SEYPEC) indicates that bunkering by fishing vessels in Port Victoria has generally followed an upward trend, increasing from SCR 1.6 billion in 2019 to SCR 2.59 billion in 2024. However, in 2025, the value of bunkering declined by 0.8% to SCR 2.57 billion, despite a 6.8% increase in bunkering volume from 186,988 MT in 2024 to 199,635 MT in 2025 (Table 9.1 and Figure 9D).

- The decline in the value of bunkering was mainly attributable to lower fuel prices. Average gasoil prices fell from US$954.74 per MT in 2024 to US$873.92 per MT in 2025, a decrease of 8.5%. Although the average exchange rate increased from SCR 14.53 per US dollar in 2024 to SCR 14.73 per US dollar in 2025, this was insufficient to offset the decline in fuel prices. As a result, the increase in bunkering volumes did not translate into higher bunkering revenues in Seychelles rupees.

- By vessel category, bunkering volumes supplied to purse seiners and supply vessels increased by 8% and 11%, respectively, in 2025. Despite these increases, the corresponding growth in bunkering value was relatively modest at 1% and 3%, reflecting lower fuel prices during the year. In contrast, bunkering activity by reefer vessels and industrial longliners drop considerably, with volumes declining by 40% and 54%, respectively. As a result, the value of bunkering supplied to these vessel categories fell by 46% and 58%, respectively (Figures 9B and 9D).

- Of the approximate SCR 2.57 billion worth of fuel purchased by fisheries-related vessels, purse seiners accounted for 94% (SCR 2.42 billion), similar to the previous year when they represented 93% (SCR 2.41 billion).

- By flag, Spanish vessels represented the largest share of bunkering in 2025 at 35% (SCR 898.7 million), followed by Seychelles-flagged vessels at 28% (SCR 717.5 million) and French vessels at 15% (SCR 378.7 million). In comparison, in 2024, Spanish, Seychelles, and French vessels accounted for 34%, 32%, and 17% respectively (Table 9.1B and Figure 9F).

9.2. Other Vessel Expenditures

- Readers should note that the figures presented in this bulletin may differ from those published previously. These revisions reflect the incorporation of historical data received from vessel agents that had not been submitted earlier to the SFA, as well as improvements to data validation procedures designed to enhance the accuracy, consistency and reliability of the statistics reported.

- Vessel expenditures, excluding bunkering costs, increased from SCR 364.5 million in 2020 to a peak of SCR 521.9 million in 2021 coinciding with the COVID-19 pandemic period when Port Victoria remained an important hub for tuna fishing, transshipment and related support services. Thereafter, expenditure followed a downward trend, declining to SCR 314.9 million in 2024. Following three consecutive years of decline, vessel expenditures recovered to SCR 397.8 million

in 2025, representing a 26% increase over the SCR 314.9 million recorded in 2024 (Table 9.2 and Figure 9G).

- The increase in vessel expenditure observed in 2025 was driven primarily by higher port-related charges following revisions to the Harbour (Port and Harbour Dues) Regulations in 2023. The revised tariff structure introduced a cumulative 75% increase over the previous tariff base, implemented in two phases between 2024 and 2025. The full implementation of the revised tariffs in 2025 contributed significantly to the rise in vessel expenditure during the year.

9.3. Vessel Port Expenditure by Vessel Type

- Purse seiners continued to account for the largest share of vessel expenditures in Port Victoria. Total expenditures by purse seine vessels were estimated at SCR 346.5 million in 2025, compared to SCR 281.4 million in 2024, representing an increase of 23%. Purse seiners accounted for approximately 87% of total vessel expenditures in both years, highlighting the continued importance of the purse seine fleet to economic activity generated by the tuna industry in Port Victoria (Table 9.2B and Figure 9H).

- Reefer vessels represented the second-largest contributor to vessel expenditures in 2025, accounting for an estimated SCR 21.9 million, or approximately 6% of total expenditures. This compares with SCR 7.5 million in 2024, representing a substantial increase of 190%. While part of this increase reflects the higher port tariff structure, operational factors also contributed significantly. According to Vessel agents, in recent years, the availability of refrigerated shipping containers in Port Victoria has become increasingly constrained. As a result, companies have increasingly relied on conventional reefer carriers to transport frozen fish exports when sufficient reefer containers were unavailable. This has led to increased activity by reefer vessels in Port Victoria and, consequently, higher expenditure on port dues, vessel services and related operational costs.

- Supply vessel expenditure increased by 17%, from SCR 12.5 million in 2024 to SCR 14.6 million in 2025. Similarly, expenditures by industrial longliners increased from SCR 13.5 million to SCR 14.8 million over the same period.

9.4. Expenditures by Cost Category

- Analysis by expenditure category indicates that government fees and port dues recorded the most significant increase in 2025. Expenditures under this category amounted to SCR 93.8 million, compared with SCR 59.0 million in 2024, representing an increase of 59%. This sharp growth reflects the phased implementation of the revised harbour tariff structure and underscores the growing contribution of port-related charges to overall vessel expenditure.

- Stevedoring expenses also increased substantially, rising by 34% from SCR 11.3 million in 2024 to SCR 15.1 million in 2025. The increase is consistent with an increase of 24% in tuna catches unloaded in Port Victoria in 2025 over the previous years.

- The largest expenditure category remained "Other Expenses", which includes a range of vessel support and operational services. Expenditures in this category increased by 18%, from SCR 244.6 million in 2024 to SCR 288.8 million in 2025. Despite accounting for the majority of vessel expenditures, growth in this category was more moderate than that observed for government fees and port dues, suggesting that the overall increase in vessel expenditures during 2025 was driven primarily by tariff adjustments rather than a broad-based rise in operating costs across all expenditure categories (Table 9.2B and Figure 9I).
